2665. Re: Using 2 Smaller Gauge Wires in Place of Large Gauge Wires

Yahoo group: SkyWires
Date: 2007-10-06 10:47:34 UTC
From: denisnh
Topic: 2642 Message: 2665

Thanks again, Stan. I mentioned this in another post. (Maybe it
should be a new topic). Do you know of anyone who has used coax for
an antenna wire using only the shield/braid? I'm wondering if it will
behave like a large diameter wire if the center conductor is not
connected in any way? Any ideas? RG-6 is pretty thick stuff. I
suspect the dielectric may cause problems or perhaps even some
parasitic side effects from the center conductor and I don't think
software modeling will will show up much.

Thanks,
Denis

From: denisnh
Topic: 2643 Message: 2666

HAH! Warm and Fuzzy, huh? As in tennis ball.... Ohh you're good.
Your analogies fit together like the stones of the great pyramid of
Giza. LOL

Erik, I assume you get the Atlatl at pet stores?

By the way, I'm probably driving everyone nuts with this question but
it just won't stop surfacing in my mind for further analysis. :-)

The idea of using a coax with the shield only as a large diameter
radiating wire antenna. Any thoughts?

Thanks,
Denis

From: denisnh
Topic: 2643 Message: 2667

Oh, regarding the crossing the Canadian border with questionable objects. This is off topic but I'll try to keep it short. When my son was a boy, we used to build and launch model rockets together. Then I came across a magazine, "High Powered Rocketry" ironically published in Canada. So I had my eye on an eight footer with composite engines that would go up and up. I called customs and asked them if I could assemble the rocket and take it across into Canada where there is a lot of launching room. No way to launch something like that in Northern New England. The customs guy said, "Sure, no problem." Then I asked about the engines and he said, "absolutely not! They are considered explosives!" HUH??? Turns out the composite engine manufacturer is in the U.S. and they send the engines off to Canada in plain boxes and about 2/3 of their shipments get through. The rest are intercepted by customs at the customer's expense. Go figure....

Regards,
Denis

At 08:27 10/6/2007, denisnh wrote:
>The idea of using a coax with the shield only as a large diameter
>radiating wire antenna. Any thoughts?

I think you could cut the coax the length of a regular
dipole and connect the shield to the center conductor at each end of
the segments and run it as a regular dipole. That would be
simple. As for using just the shield NOT connected to the center
conductor -- well, I think you might have trouble keeping the shield
totally disconnected from the center conductor -- keeping them from
touching -- and beyond that, I don't think it would operate any
differently, but that's just my gut feeling. I've never tried it.

Oh, another thing that can be an advantage with the atlatl is if you
have a dog that fetches. My dog is an excellent Frisbee dog and goes
after anything. He's part coon hound and very fast with long legs.
When setting up a wire, I can just make like I'm playing with my dog
by slinging ordinary tennis balls until I'm sure nobody is looking and
grab the tennis ball with the leader string attached and sling that up
into the tree. I just hope my dog doesn't climb the tree after it.
Make for a nice diversion for a "covert" project. :-)

Subject: [SkyWires] Re: Feed Arrangement
for Operating the Loop as a Vertical
Antenna

Oh, another thing that can be an
advantage with the atlatl is if you
have a dog that fetches. My dog is an
excellent Frisbee dog and goes
after anything. He's part coon hound and
very fast with long legs.
When setting up a wire, I can just make
like I'm playing with my dog
by slinging ordinary tennis balls until
I'm sure nobody is looking and
grab the tennis ball with the leader
string attached and sling that up
into the tree. I just hope my dog
doesn't climb the tree after it.
Make for a nice diversion for a "covert"
project. :-)

2671. Re: Feed Arrangement for Operating the Loop as a Vertical Antenna

Yahoo group: SkyWires

Thanks Earl. Just saw your reply after posting more requests for advice on this. Now that you mention it, the dielectric in RG-6 is some pretty sorry looking foam. Your response made me realize that this inferior dielectric will eventually get warn away and short the center conductor with the shield. Maybe I'll try a small vertical loop as a test benchmark and see how it does. Of course there may be a way to heat up the center conductor using high current DC and pulling it out as the dielectric melts. But with three hundred feet of cable??? Nah, bad idea.

2672. Re: Feed Arrangement for Operating the Loop as a Vertical Antenna

Yahoo group: SkyWires
Date: 2007-10-06 15:02:03 UTC
From: denisnh
Topic: 2643 Message: 2672

Hi Reverend. I just never got used to setting up wire antennas and how it must look to casual observers. I mean, putting up big, heavy copper wires that conduct a lot of current must make some onlookers a little edgy and I tend to try and be a good neighbor. On the other hand, if you tell them what it's for, they start blaming you for everything from TVI to crop circles. I could always say it's a geomagnetic disturbance sensor that I'm helping my college daughter with as a school climate project. :-) I do have a weather station on my roof so that would fit in nicely with my "cover". LOL (You know, that just might work!)

Most of the people here are pretty cool. There is one neighbor to the side of me, though, and the nosy #*@%$*& people just can't mind my own business. It's pretty rural and wooded here, but I can hear them talking away about what I'm doing as if I can't hear them. I usually make a comment regarding their conversation and give a cordial wave as I head back into the house. I already have five attachment points to this loop with at least two more to go so it's looking pretty involved.

Let's face it, running heavy copper wires through trees does look pretty scary to some folks. If they came over to ask about it I would just tell them it's an MW receiving antenna for MW. But they just watch thinking I can't hear or see them. It get's pretty annoying and I have absolutely nothing in common with these folks.

Night time deployment of antennas always turns into a disaster. Leader strings and ropes get tangled or broken and and can't get a good aim on that fork at the top of the tree.

What are ya gonna do. :-)

2673. Re: [SkyWires] Re: Feed Arrangement for Operating the Loop as a Vertical Antenna

Yahoo group: SkyWires
Date: 2007-10-06 15:28:02 UTC
From: Erik Weaver
Topic: 2643 Message: 2673

Hey Denis,

I haven't looked up your call, assuming I've seen it. I'm guessing you live in NH?

I do in fact have a fascination with the pyramids --who doesn't?-- so maybe I was involved in the project in a past life? Hope I was a whip wielder! ;)

Didn't my web page have the link where I got my atlatl? ......I'll be very disappointed if not...... Uh, yes, very first link at the top of the page:

http://www.chuckit.com/products/chuckit/chuckit.html

It is a doggie toy, so yes, I'd look in pet stores, especially if there are big ones near you, or you go there anyway. I ordered mine on-line however. I *think* I ordered my atlatl online at that "Chuckit" web site, but maybe it was a different on-line store. I recall the ordering and shipping all took place smoothly. I suggest clicking their "Contact Us" link and call them. They can either take an order over the phone or tell you if there is a pet store close to you. If you Google "Chuckit dog toy" I expect you'll get plenty of usable hits. (You do -- I just did anyway, each of the first three I look at allowed me to order it on-line, and they are only a little over $10. Cheap at half the price!)

There are two versions, maybe three, with length being the major variable. Longer length equals greater force of course, and therefore greater tree-clearing height. I recommend one that is at least 2-ft long. I think mine is close to 2-1/2-feet long. 29-30 inches seems about right.

When you get your tennis balls or antenna launching you can use old 'dead' ones that are sometimes almost free at garage sales. Cut them open and put in some sand, lead singers (perhaps best--as you'll see when "loop string" time comes), or BBs, something like that to provide a little extra weight (*NOT* filled! -- you still have to chuck this thing 100-feet!) and then seal it with silicone or hot glue, something like that. If you leave a little loop of fishing line, etc, you'll have a handy little loop to tie your antenna lift-rope's "leader line" to, which is far easier than trying to tie a string around a round tennis ball! (The tie-loop is highly recommended!) ;)

I expect that discussion is part of the air gun page, or the links one that page. It does have some links showing what others have done.

The basic idea is to get a few onces of weight in the tennis ball, get a loop of string firmly inside the ball (or through it), and hanging outside the ball, that will be strong enough to take repeated "casting" and then launch with a light-weight "leader" string. This allows the ball to fly most effectively while reducing drag form the line, which is actually a major factor. Drag seems to increase on an exponential scale, so 1/2" rope is many times more difficult to launch than fishing line.

Then once you get the ball over the tree if it hasn't reached the ground you pull it up a foot or so and let go, and repeat until it works its way out of the tree. This is another reason to have weight inside the tennis ball. (Bright colored balls are nice at this time too.) I've made a "perfect" shot with one of those small crossbows but the bolt was too light to work it into reach. So it was for naught.

Once you have the tennis ball back in hand, tie a braided string to it and haul that over the tree. Then tie a rope to that string and pull your lifting rope over the tree, and your antenna is up! (On that end anyway.) It actually works quite well for reasonable heights. But you can most certainly achieve greater height with much less effort using the air gun. No question about that. However, that said, the atlatl is far easier to transport, has no moving parts, appears "warm and fuzzy" to the men with guns and badges, and will easily get the tennis ball over limbs 40- and 50-feet high in the tree. I am confident 100-feet isn't out of the question, but so far that has taken a some effort and practice, whereas getting that 40- and 50-feet height is almost as easy as tossing an orange into a trash can in the kitchen. It is almost a "gimme"!

Both methods are a lot of fun however, and I recommend both. But it sounds to me like the atlatl will serve your needs best. Canada and whatnot. Assuming you'll be pleased with easily reaching 40- and 50-foot tree limbs. I personally am. That is more height than many amateur radio home-antennas and quite acceptable for portable operations.

Coax as Antenna

Sure, that'll work well -- for a while anyway. It will be heavy however. Another consideration is weather, assuming it'll be outside. Coax shielding is assumed to be protected inside it's outer cover by design. It is made up of tiny inter-weaved strands of wire. Sounds like a lot of corrosion opportunity to me.

I think I'd rather try contacting my local utility company or coop first and see if they have any "drop" or used wire heading to the dump, and if you can get it for salvage price, or for free-for-the-hauling, thus saving them disposal fees. (Of course they may recycle and get the weight of the metal back -- that may depend if they are a government operation, who need not care about profit --that is what tax-payers and jack boots are for-- or a smaller coop trying to keep costs low.)

Take care and have fun!
Erik n0ew

PS: Visit this web page of mine and see if this special event sounds like fun to you -- my friend and I sponsor it every year over Memorial Day weekend (3-day weekend every Spring):

http://www.n0ew.org/k0s/

If "The Strange Antenna Challenge" sounds like fun, you have until May to plan your own "Satellite" special event if you like. You can do it solo, with a group of friends, or even as a club event and try to gain membership and/or media attention. Or, just listen for us that weekend and work us with your new HF antenna. We'll be the "K0S" special event station. Satellite stations have to use their call sign slash K0S (see FCC rules), and more do so each passing year! It is a lot of fun!! :)

2674. Re: [SkyWires] Re: Feed Arrangement for Operating the Loop as a Vertical Antenna

Yahoo group: SkyWires
Date: 2007-10-06 15:30:30 UTC
From: Erik Weaver
Topic: 2643 Message: 2674

Perfect! Sounds like fun too.
Erik n0ew

2675. RE: [SkyWires] Re: Feed Arrangement for Operating the Loop as a Vertical Antenna

Yahoo group: SkyWires
Date: 2007-10-06 15:33:16 UTC
From: ag0k@ag0k.com
Topic: 2643 Message: 2675
Attachments: 1 described; binary payloads are missing from this source WARC

Dear Denisnh

I definitely know what you are talking
about.

My wife and I live in a church Manse
[parsonage].
After I got here in April and the
members were helping
me unload our stuff one of the deacons
asked about
my radios. He turned out to be a Tech
and by the
end of May he was so hooked by HF he
went and upgraded
to a general.

In any event, that deacon along with two
other deacons put
up a 135' Zepp fed with 450 ladder line
and a 144' loop which
I feed with 300 ohm twin lead. Both
antennas are constructed of
the 30% copper weld from the wireman.

Several members have come by the manse
to visit and the see
the radios and I advise them that I am a
ham radio operator.

The next question I get from them is
where is the Antenna.

I just love the 16 gauge copper weld.
Get it up high enough
and it seems to just disappear.

Good luck on your antenna projects.
73's Clint AGØK

2676. Re: [SkyWires] Re: Feed Arrangement for Operating the Loop as a Vertical Antenna

Yahoo group: SkyWires
Date: 2007-10-06 15:35:06 UTC
From: Erik Weaver
Topic: 2643 Message: 2676

My #14 copper stranded "antenna" wire did catch the light at first. But after it aged it was almost invisible. I *knew* where to look and I had trouble finding it. Others will have had similar experiences I'm sure. Of course, you still have to get through the "shinny" stage. Maybe you could leave a coil of it hanging on a tree over the winter and deploy late winter/early spring before the leaves get thick.

2678. Re: Feed Arrangement for Operating the Loop as a Vertical Antenna

Yahoo group: SkyWires
Date: 2007-10-08 03:47:30 UTC
From: denisnh
Topic: 2643 Message: 2678

Hi Eric. Yeah, also speaker wire with the transparent insulation shows up amazingly well, especially when the sun shines off it.

I few years back, I set up the "Four Buck Antenna" in that big 80' pine about 75' from the house. I got some surplus #14 copper stranded with brown insulation at a great price from a surplus store and I bit the bullet and bought NEW 300 ohm twin lead, exterior grade, from radio shack. That twin lead is excellent by the way. It holds up very well and I've built some DCTL antennas from it that worked great also. I've actually placed a wooden X-frame to hold the loop open and hoisted them up in a nearby tree. I used them for receive only, but they were very quiet and actually seemed to have some gain, which is one beef I have regarding certain loops.

Anyway, getting back to the Four Buck Inverted-V, after I finished the installation, I would try to point it out to people visiting, and I could not for the life of me see it! We would have to walk closer and then I would scout for the wire-end insulators before I could finally find the antenna elements.

I also die good quality nylon ropes with ordinary fabric die (Ritt I think?, either black or brown, and they would disappear also. I've always wanted to try "tie-dyeing" rope with various camouflage colored dyes. If I can find some extra time, I may still try that. If it worked, that would be one really neat looking rope!

Erik, great idea on the strange antenna event. You ever listen to coast-to-coast AM radio, speaking of pyramids and past lives? I forgot to check, but is your email posted on your web site?

Thanks,
Denis

2679. Re: [SkyWires] Re: Feed Arrangement for Operating the Loop as a Vertical Antenna

Yahoo group: SkyWires
Date: 2007-10-08 05:49:57 UTC
From: Erik Weaver
Topic: 2643 Message: 2679

Hey Denis,

Yes, my email is on my web page.

Yes, I've been a big coast to coast fan for well over ten years. No one can top Art! Ian does a pretty good job. Noory not so much, but I have to put up with his poor skills to hear the good bits.

Erik

2680. Re: [SkyWires] Re: Feed Arrangement for Operating the Loop as a Vertical Antenna

Yahoo group: SkyWires
Date: 2007-10-09 18:36:18 UTC
From: WILLIAM STEFFEL
Topic: 2643 Message: 2680

Tell them what I tell my neighbors. It is a Hyperdimensional reflector so your space brothers can find you to take you home. The neighbors will avoid you like the plague. Dont forget to use the term "Hyperdimensional",it sounds scarey.

Subject: [SkyWires] Re: Feed Arrangement for Operating the Loop as a Vertical Antenna

Hi Reverend. I just never got used to setting up wire antennas and how it must look to casual observers. I mean, putting up big, heavy copper wires that conduct a lot of current must make some onlookers a little edgy and I tend to try and be a good neighbor. On the other hand, if you tell them what it's for, they start blaming you for everything from TVI to crop circles. I could always say it's a geomagnetic disturbance sensor that I'm helping my college daughter with as a school climate project. :-) I do have a weather station on my roof so that would fit in nicely with my "cover". LOL (You know, that just might work!)

Most of the people here are pretty cool. There is one neighbor to the side of me, though, and the nosy #*@%$*& people just can't mind my own business. It's pretty rural and wooded here, but I can hear them talking away about what I'm doing as if I can't hear them. I usually make a comment regarding their conversation and give a cordial wave as I head back into the house. I already have five attachment points to this loop with at least two more to go so it's looking pretty involved.

Let's face it, running heavy copper wires through trees does look pretty scary to some folks. If they came over to ask about it I would just tell them it's an MW receiving antenna for MW. But they just watch thinking I can't hear or see them. It get's pretty annoying and I have absolutely nothing in common with these folks.

Night time deployment of antennas always turns into a disaster. Leader strings and ropes get tangled or broken and and can't get a good aim on that fork at the top of the tree.

What are ya gonna do. :-)

What a hoot! :-) Try to fit the word "Quantum" in there somewhere for added effect. Or if you don't mind being taken away by the guys with the white coats, tell them it's the Quantum Time Deflector Loop which is connected to your time machine.

I told my wife I would tell the neighbors that wire is a UFO Detector, but my wife said, "DON'T YOU DARE!". HA HA

Welcome also, and I agree, that there are no stupid questions. As an old Master Chief once told me while I was in the Navy " The only stupid question is the one you don't ask." So ask away.

2687. Aluminum Wire

Yahoo group: SkyWires
Date: 2007-10-14 22:55:18 UTC
From: Steve Holman
Topic: 2687 Message: 2687

Hey Guys, I am building a 600+ft loop in the back patch, I have some copper wire on hand but this tends to strech. I have access to some aluminum fencing wire that is intended to be put up under tension and I also would have more than 600ft available to put up and therefore my loop could be bigger(Good!!)

What do you say, any comments?

I know that Copper conducts better but Aluminum is not far different and would allow more tension to reduce sag and streching. I have to keep the wire above the Farm Equipment

How do you plan on connecting your feedline? You got aluminum
feedline?? Copper won't solder to aluminum. I assume the aluminum
fencing is solid?

Solid wire, aluminum or copper is not good for antennas as it will
break from the flexing.

Get stranded insulated copper wire. Dont worry about stretch, use open
feeders instead of coax. I have been using common THHN stranded
insulated copper house wire for antennas. Never worry about stretch
cause it doesn't stretch much even on long loops. Its tuff stuff too,
never had an antenna break yet.

Keep your fencing wire for fencing.......

There are 2 problems with using coax as antenna wire.
1. Coax is expen$ive
2. Coax is HEAVY

I really cant imagine a loop being made of coax, way too heavy

I once had a IAC 75 mtr Bazooka antenna which is made mostly of small diameter coax. Very heavy antenna. I had it supported in the center and it sagged badly anyway from the weight of the coax.

Stan Thanks for the comments.

Actually Solder IT company makes a Solder for Copper/Aluminum Joining.
I was going to use some of that Product.
As for the solid Copper Itcome off the same roll of Wire I had up for
7 - 8 years as a long line SWL antenna before I got my License never
had any breaks, it just streached but it was just one long run. My
loop is in the open and has no tree limbs or Etc. to rub or cause
extra stress on the antenna. Best of all this is the Good Stuff (FREE)
and I have it. The Aluminum is available for 1300+ ft for $21+change
at Tractor Supply so I had thought of trying it. I have all my spare
change in the Supports right now so Buying a $45.00 Roll of THNN
Stranded wire is a bit much as I have a very strict budget on this
ant. I Had thought of using aluminum Fence wire as it would give me a
larger All Band Loop and Larger is Better you know (:

The Loop will be fed with a 100Ft of 450 Ohm Ladder line to a 1:1
balun and 5Ft of Coax into the Shack. It is supported at 8 Corners at
Aprox 30Ft by Grey PVC Conduit set at an angle that results in the
wire being under tension like a Draw String in a bag. I call it a Post
Tension Loop. I hope to have it finished in a week or so if I use the
Copper or 3 to 4 weeks if I move the Supports for the larger Aluminum

Loop.

We Shall See.

Subject: [SkyWires] Aluminum Wire

Hey Guys, I am building a 600+ft loop in the back patch, I have some copper wire on hand but this tends to strech. I have access to some aluminum fencing wire that is intended to be put up under tension and I also would have more than 600ft available to put up and therefore my loop could be bigger(Good!!)

What do you say, any comments?

I know that Copper conducts better but Aluminum is not far different and would allow more tension to reduce sag and streching. I have to keep the wire above the Farm Equipment

For what it's worth, I've had very good luck with aluminum fence wire antennas. Served well throughout the year including winter, ice storms, etc. A quarter mile spool is reasonably priced at TSC or other farm stores and will make a lot of antenna!
As for feedline connection I used a mechanical connection (bolt, washers, nut) and coated it with no-ox grease used by the military and communications companies for ground connections etc.
Worked well for me, good luck on your's.

Hi,

Aluminium wire is very tempting .... light, strong, and relatively cheap. However the problem is in the connections .... especially connecting aluminium to copper. Aluminium was used for house wiring in the past ... in the 70's I believe, and was the cause of a lot of grief .... and is now banned in many jurisdictions. The problem was always in the connections. For practical reasons the most common connection either to other wires or devices is with some kind of pressure connector. I would check with your electrical supply house for specially designed (for aluminium) crimping devices and tools as well as no-ox grease.

My personal position on wire for antennas and or ground systems is to use the best wire, (copper) and best practices. Putting in a ground system or putting up a large wire antenna is a lot of work that I would not want to

revisit very often ... I want it to last with as little need for maintenance as possible hi hi .... best investments are for the long term hi hi.

I have used the aluminum wire for HF antennas and VHF beams.
I solder with the special compound from Solder-it to solder to the aluminum as well as nut-and-bolt and crimp lug with the No-Ox. Then seal the joint with weather seal compound. either the one from Rad Shack, the rubber self sealing tape or an old time sealer- DUCK Seal IIRC. I found some at Home Depot a few months ago. Have used it for many years. I apply it over the black plastic tape.

Healthfully yours,
Don W4BWS

I will try this again, my last message didn't post.

Hi Jim and Eveyone,
Aluminum wire was used in older mobile homes and was quite a problem. Many had electrical fires. My Mom owned one of these homes over 25 years ago. One outlet would make the wall board very hot. I would remove the outlet cover plate and tighten the electrical/mechanical wire connections but after a relatively short period of time the wall board would start getting hot again and I would need to tighten the electrical/mechanical wire connections again.
It was a never ending project.
I have since learned they had a repair method that worked well by crimping another type wire (possibly copper) to the end of the aluminum wire before it went under the brass screw.

This is and was very true...
But... With an antenna you are not running high current at joints.
So what does house wiring have to do with outside antennas?

Hi Dean,

The experience with aluminium house wiring is simply illustrative of the problem with aluminium at contact surfaces and some of the solutions that experience generates ... (the out-of-doors environment with its heat, cold, wind, and rain, exacerbates the problem) . You are wrong about the current at antenna joints .... the current can be considerable. Take the simple example of feeding the wire antenna at a 50 ohm impedance point. If you use the simple formula of I = W/R you can calculate that 5 watts will produce .1 amp at the joint, 100 watts will produce 2 amps, and 1KW will produce 20 amps. I think I would treat the connections with care (I have actually seen joints blown to smithereens) hi hi.

Indeed one can run VERY high current on an antenna at legal limit
levels.10 -20 amps is not uncommon depending on band, antenna etc.
Dont believe me?

Run your favorite antenna modeling software and get the actual figures....

Using aluminum wiring doesn't make sense to me for an antenna. However
there will always be those who take the cheep way...

Since you seem to want to be an expert on current, please explain to us what difference the frequency makes or voltage makes when it comes to the current handling capacity of a wire???

I for one would like to know how 10 amps of current at 60hz differs from 10 amps of current at 14mhz.

I personally am not worrying. I use copper wire for all my wire antennas. I know from 47 years of experience that the antenna system is the most important part of a ham station. It is the LAST place I would cut corners to save a few dollars.

Putting up antennas, ESPECIALLY a loop takes planning and work. I would not jeopardize the performance OR longevity of any antenna just because I wanted to save a few $$$ on wire....

There will always be hams that will cut corners. These are the guys that use RG58 coax, aluminum fencing wire, dog fence wire,radioshack coax, clothes line rope for end support. These are the same fellows that put their 75 mtr antennas at 30 ft high, and load up that same 75 mtr antenna on 160 mtrs. And then blame propagation cuz no one can hear them.

2708. Newbie Questions about a Skywire Design That is Low to the Ground

Yahoo group: SkyWires
Date: 2007-10-19 17:29:01 UTC
From: Karl
Topic: 2708 Message: 2708

I'm new to all this and could use some help. What do you think of my plan?

I live in a single storey house in an area where the CC&R's and the city make erecting an antenna difficult. In addition, I have no trees on my property.

What I do have is about 200 ft of perimeter to the house and wooden eves to which a wire antenna could be stapled. The house is not quite square but rectangular, measuring 47 ft x 51 ft.

All of this makes me think a skywire loop may be the way to go except that 200 ft is neither correct for a 40 meter loop (142ft) nor for an 80 meter loop (272ft). It is actually tuned to 5.1 MHz (59 meters) by L=1005/freq. How much of a problem will this be?

I'm thinking of using ladderline so I could access a range of bands. Unfortunately, the house is a single storey so the ladderline will only drop about 8 feet into the window of the shack. How big a problem is that?

I'll be using a Kenwood TS-440 with internal antenna tuner. Don't you think I will need an external one as well?

Thanks in advance for your thoughts.

Hi Stan,
FYI:
at 60 Hz the current travels thru the entire wire. At RF Freqs there is "Skin Effect" the current only travels on the outside perimeter of the wire/conductor almost like it is a hollow pipe conductor.

>
> Dean W5GXL
> dean@...

Since you seem to want to be an expert on current, please explain to us what difference the frequency makes or voltage makes when it comes to the current handling capacity of a wire???

I for one would like to know how 10 amps of current at 60hz differs from 10 amps of current at 14mhz.

I personally am not worrying. I use copper wire for all my wire antennas. I know from 47 years of experience that the antenna system is the most important part of a ham station. It is the LAST place I would cut corners to save a few dollars.

Putting up antennas, ESPECIALLY a loop takes planning and work. I would not jeopardize the performance OR longevity of any antenna just because I wanted to save a few $$$ on wire....

There will always be hams that will cut corners. These are the guys that use RG58 coax, aluminum fencing wire, dog fence wire,radioshack coax, clothes line rope for end support. These are the same fellows that put their 75 mtr antennas at 30 ft high, and load up that same 75 mtr antenna on 160 mtrs. And then blame propagation cuz no one can hear them.

Hi Karl,
I think it will work well. Try it !
How will you transition from the ladder line to the Kenwood TS440 ?

Subject: [SkyWires] Newbie Questions about a Skywire Design That is Low to the Ground

I'm new to all this and could use some help. What do you think of my plan?

I live in a single storey house in an area where the CC&R's and the
city make erecting an antenna difficult. In addition, I have no trees
on my property.

What I do have is about 200 ft of perimeter to the house and wooden
eves to which a wire antenna could be stapled. The house is not quite
square but rectangular, measuring 47 ft x 51 ft.

All of this makes me think a skywire loop may be the way to go except
that 200 ft is neither correct for a 40 meter loop (142ft) nor for an
80 meter loop (272ft). It is actually tuned to 5.1 MHz (59 meters) by
L=1005/freq. How much of a problem will this be?

I'm thinking of using ladderline so I could access a range of bands.
Unfortunately, the house is a single storey so the ladderline will
only drop about 8 feet into the window of the shack. How big a problem
is that?

I'll be using a Kenwood TS-440 with internal antenna tuner. Don't you
think I will need an external one as well?

Thanks in advance for your thoughts.

Hi Karl...
Our ham radio club had a guest speaker recently for our version of your fcc... He gave us a suggestion regarding installing such things as towers... which made sence to me....
He suggestion was to start out small and simple... Remember ham radio is going to be, or should be, a life long hobby.. Don't try to put up a huge antenna right away...
Start out small and simple... Consider putting up a simple random wire first and let your neighbourhood get used to that first...
The following year, put un a single or two sections of tower but only put up a 2 meter ground plane antenna on it.... possibly you can attach the house end of your random wire antenna to it as well...
In short, avoid putting up large antennas during your first few years as an amateur.. Let your neighbourhood get used to you, as an amateur, slowly....

Ace,

You are totally correct about the skin effect that is why cable television companies go through the trouble of bonding copper to the outside surface of their aluminium coaxial lines (meaning the center conductor).

Back in the early 60's my brother and I use to build crystal sets with giant loops of aluminium wire... we found we didn't even need a crystal because that 'flakey white stuff' acted as the crystal! When we cleaned the wire up we needed the crystal... amazing discovery for us at that stage of learning really...

I have use aluminium as antennas many times but they must be cleaned often, if not they can give a mass of rectification (spurs and other garbage) on receive and TVI on transmit...

Sure build the antenna but be aware of the problems that might show up later down the line. I use number 8 copper for everything these days simply because I can AND I don't have the physical ability to search down and repair these types of problems... I also don't need TVI... And I simply don't trust the wide band finals in modern rigs as they beg for out of band signals...

Hi Karl,

Here's pitching my two-cents against the wall!.... As always, "your mileage may vary," heheh....

I think you are right; I think you have a good candidate for an eave-loop antenna. Of course, you won't know for certain until you try it. If you work regional nets it may work pretty well for that on the lower bands (being low to the ground you'll get some NVIS effect). Sometime you might play around with laying wire on the ground under the loop. You may find that changes it somewhat. If you like the change, build flower boxes along the entire perimeter and line the bottoms with copper sheeting! ;) Pretty, effective, and it smells nice! Perfect! LOL

Don't worry about the rule-of-thumb formula. That doesn't take into account your building and the effects it will have upon the antenna system and radiation pattern it develops. Such things are nearly impossible to accurately model. You didn't mention if you had metal siding, but either way, I'd still try it!

Instead of worrying about formulas and what-not, try to identify obviously bad ideas and avoid them. (Such as running ladder line up along the metal downspout -- clearly *not* a recommended practice!)

You will be relying on the old "get as much wire in the air as you can" theory. As you increase the area of a loop antenna it generally works better for capturing radio signals. The closer it forms a circle the better, but a near square should be just fine, as are reasonably equal-sided triangles. There are differences between these options of course, and the ARRL Antenna Book is a good starting place to discover more about them, but the bottom line is that doesn't really matter to you. It sounds as if your options are severely limited.

(Although educating yourself is always a winning idea, and the Antenna Book is fun just to thumb through; especially what with winter coming!)

If you have an attic you can try stringing up wire there. Most likely the only vertical antenna you may get away with is a flagpole (which can work well, so you may want to deploy two antennas eventually -- but save that project to follow the spring rains so the soil is easier to work with).

And with the holidays upon us you have the perfect opportunity to run along the entire length and breadth of the house, stringing wire! Both Halloween and Christmas are valid candidates for holiday lights or other decorations. You'll just happen to be running a "special" wire too! ;)

> I'm thinking of using ladderline so I could access a range of bands.

Yes. Wise man!

However, do ensure it remains "balanced." This means no metal or magnetic materials nearby. "Nearby" means a minimum distance (preferably open air, with the fewest non-conductive supports needed to maintain stability in the weather) of "one-width" of the ladder line. Just lay a ruler on the ladder line and measure the outside distance from one wire to the other. If you have the common 450-Ohm ladder line that should be something like and inch or so. I've never measured mine, but that has to be in the ballpark.

That is the minimum; not optimum. If you can obtain several times this distance, that is better and worth doing. It is a exponential kind of thing, as opposed to a simple arithmetic slope. (Doubling the cleared distance may decrease ill effects by four times, for example.)

"Opposite and equal paths of current cancel radiation." Remember this from E-H wave discussion? This is the principal behind all balanced line. But if it gets too close to metal or a magnetic source, it will no longer be "equal and opposite," therefore it will cease being transmission line and instead become a radiating element of your antenna system. Not generally the goal when using ladder line ;)

> Unfortunately, the house is a single storey so the ladderline will
> only drop about 8 feet into the window of the shack. How big a problem
> is that?

Depends upon how you transition from the (properly supported and routed) outdoor ladder line through the window to your station. It cold be just fine or a train wreck with RF flying hither and yon, crackling into your TV and burning your lips should they contact a metal microphone. (If you use a mic.)

But there are plenty of good ways to make this transition. Fear not!

How far away is your station from the window in question? A few feet? Ten feet? Thirty feet? The "answer" is best modified for each solution.

If you are just a few feet away from the window then you can either get some high-quality low-loss coax and run the 5- or 10-feet with that coax. Run the coax out the window and into a balun designed to also

transition from coax/ladder. You'll suffer losses in the coax when the swr is high, but if it is a short run and really good coax that won't really matter.

("QEX" ran an interesting article in which it was suggested wiring a voltage and current balun in series provided the best of both worlds, with little to no ill side effects. I haven't experimented with this yet, so I won't comment further, but the story made good sense!)

If you are connecting to your station as balanced line, again take high-quality low-loss coax and make a balanced line out of it. Go to a reputable dealer, like Davis RF or The Coax Man (Google them if they aren't already bookmarked on your browser). Find as high a "characteristic Ohm" value as you can. It seems to me I saw one of them had 125-Ohm coax, and that was the highest I found. But I didn't call either one to ask if they had higher Ohm coax available. It wasn't the lowest-loss coax, but of a middling-high quality. I wouldn't plan to run it 50- or 100-feet!

The ARRL Antenna Book has a diagram showing how to hook this up.

Both lengths of coax are equal. Solder the shielding together at each end. Outdoors you do nothing with the shielding and just use the two center conductors exactly as if they were any other balanced line (except they are shielded, so you can run them through walls and what-not, just as you can regular shielded coax). Indoors, connect the shielding to your station ground.

(Which should in turn be connected to an outdoor ground rod, which in turn should (must be by the NEC) connected to the utility ground, and a chemical-burn is the best joining technique and will last essentially forever because it "welds" the dissimilar metals into one another -- seek a qualified electrician for all this work if you don't already know exactly what I am talking about. You may or may not need a permit. You may or may not be required by law to employ a licensed electrician. Call you attorney or city zoning/permits department for legal guidance.)

You use the highest-Ohm coax because its effective nominal Ohms will be half of whatever you start with.... 125-Ohms / 2 =~ 62.5-Ohms; 75/2 =~ 35-Ohms; 50/2 =~ 25-Ohms. The goal is to minimize the difference between your ladder line (most likely 300- or 450-Ohms) and what you create with coax. Some will recommend a 1:1 balun between the two types of balanced line. Unless you over-heat it, and provided it is designed properly for the frequencies for which you operate, it shouldn't hurt, and at higher frequencies it may even be beneficial. I'm not convinced you'll note any difference on the lower bands (40/80) but I'm far from a balun expert. The ARRL Antenna Book.... ;) You may also point your browser to http://www.cebik.com/ when seeking answer to questions such as these. Good info there! Highly recommended!

Or buy shielded balanced line and follow the manufacturer's instructions for proper use.

> I'll be using a Kenwood TS-440 with internal antenna tuner. Don't you
> think I will need an external one as well?

Maybe yes; maybe no. I'd lean toward the "yes" for all-band use. The reason is the wide range of complex impedance (simply meaning both "pure resistance" --the "good stuff" we like as hams!-- and reactance --resistance to alternating current, such as say, oh I don't know... *RF*!-- will both be present, and in wildly fluctuating ranges to boot, accompanied by drastic differences in both voltages and Ohms).

Whatever device is connected to the shack-side of this antenna system has to be able to deal with the upper/lower extremes of both voltage and Ohms. If not, either the device will be damaged or simply unable to "tune" the antenna system. ("Tune" means to obtain a successful transformation of complex impedance from what ever is presented to the device on the "antenna" side, and convert this into a range into which your XCVR is designed to operate into without damage.)

Built-in tuners are known to have smaller ranges of complex impedance conversion than stand-alone transmatches. You can use two transmatches in-line if you wish (a stand-alone transmatch and the internal tuner). Just pay attention to how each works. I'd only use a stand-alone with my XCVR's internal tuner if the stand-alone was either a manual, or an auto-tuner with a "lock" engaged. One variable at a time, please!

(I have in fact done this fairly often and have never experienced any trouble or harm to my equipment. You can use the stand-alone transmatch --almost always a manual design in my case-- to obtain an impedance match on the band you are using, and then use the XCVR's internal tuner to quickly and easily hope around inside that band. Works fine. You do incur slightly greater losses. Electricity heats metal as it moves through it. We cannot get around this, because this is the nature of moving electrons, but that represents a small loss. Greater losses can take place too. This is most common when really pushing the limits of your transmatch. For example, if the coil is not of sufficiently large physical size, it will have trouble matching a very low impedance (say 5- or 10-Ohms, for example). Losses increase (the "coil-Q" is inferior at that frequency) as compared to using the same transmatch at a different frequency, or using a transmatch designed to operate efficiently at that impedance.)

What was the question? :)

For this reason you may wish to keep on hand one or more extra lengths of transmission line (of the same type entering your impedance matching device on the antenna side). By altering the length of the transmission line, you will likely find some previously un-tunable frequencies can be successfully "tuned."

(Good candidates are lengths of transmission line that equal 1/8 and 1/4 of a wavelength ("WL") --electrical, not physical-- at/near the frequencies you are having trouble matching. Set them up so you can use them in any combination: either the 1/8- or 1/4-WL alone, or connected

together providing a 3/8-WL shift. Put away the slide rule -- you need just enough extra length of transmission line to shift the current "unmatchable" impedance within the "matchable" range of your transmatch.)

Staples?

You need not worry about them. Yes, little bits of metal "barb-wiring" your loop antenna is not a common commercial antenna design. Then again, actual barb wire fences have been successfully employed as antennas! You're loop will likely be just fine, so go ahead and just staple it to the wooden eaves. Of the things to worry about, this is not one.

A somewhat related idea, is the magnetic coil loop antenna. That is wrapping more than one turn around your house. I've not played with those so I will not comment, other than to say it is something you may wish to research.

Best of luck, have fun, and report back to us how it works!

Karl Moll wrote:
> Well, I think I need for you folks to tell me. I haven't a clue as to
> what's needed Thanks..

IMPORTANT BIT:
---

1. Read your XCVR instruction manual. I've not used one like you have. Determine the safe ranges it will operate into (meaning "load impedance").

1(b). Especially determine if it has "idiot circuitry" -- a fail-safe that is supposed to cut back power (or sometimes turn off) the XCVR if you operate into a load that will damage it. I really like these! It leaves you free to experiment!

The remaining steps are less critical after those above this point have been found to be "idiot proof" (*Always* a good thing! Myself included! A man's got to know his limitations, and with radio antenna work, part of that is knowing where your worse-case misstep still cannot destroy your $1,000 or $2,000 XCVR!)

2. Buy the wire and ladder line, and coax if needed. Connectors, borrow step ladders, etc, etc. In other words get all the physical supplies together. If possible this includes a fellow ham to help, and ridicule you good naturedly when you do something silly! That's what friends are for!

2(b). Supplies such as wire/coax: buy too much, and always cut them off longer than you need. Aways, always, measure twice and cut once.

2(c). Put an ohm meter on your coax and ladder line before using it. You are simply testing for proper continuity. Ladder line, the two opposing wires are in fact an open circuit (pretty much a given! -- I hope!!), and each wire by itself is a closed circuit. Same with coax. Open circuit between the inner conductor and shielding. Closed circuit from one end's center conductor to the coax's opposite end center conductor. Test this remains true after installing _each_ end's connector. Now is the time to eliminate simple problems like these! (It is quite upsetting to stand there with a "bad" piece of coax and not knowing which end to cut off and re-do! This is where your 'friend' will laugh, perhaps --if you are fortunate-- doing a spit-take or shooting hot coffee out his nose, thus entertaining you for your price of admission!)

3. Start by your shack window. Start stapling up the wire (along with Halloween decorations if you are so inclined!), and continue all the way

around the house. Personally, I'd toss the free-end of my wire through the window, shut the window on it, and start from there. This pretty well ensures I'll have too much wire on that starting end.

4. Secure your loop wire and the ladder line to one another. Supporting them is key. Do not stress the connection itself, which is likely just soldered or wire-nutted together. Neither is a strong physical connection, but rather just an electrical connection.

5. Determine how to transition from the ladder line through the window, and do that. Keep the ladder line distance from metal things. Like aluminum window sashes! ;)

6. Hook up your ladder line (or coax, depending upon the preceding step) to your stand-alone transmatch. In turn, connect this to your XCVR.

7. Finish the station set up. Power supply, grounding, etc.

8. Test the XCVR into a dummy load. If all is well, measure your transmission line just before it connects to your transmatch. This is a loop antenna so it should show as a closed circuit.

9. If all is well, double check all your connections.

10. Fire 'er up Floe!

;)

Hi Karl,

From what you describe you're antenna will be a 'stealth' horizontal loop 200' in diameter fed with a short length of balanced feed line (I would use 300 ohm TV line ... in keeping with the stealth aspect). The antenna should be easily tuned to just about any HF band with reasonably good efficiency. Since it will be quite low to the ground ... eg 10-15' it will be a bit of a cloud burner .... but not to worry. You will have no difficulty making all kinds of interesting contacts.

It will indeed need the antenna tuner since it is not naturally resonant on any particular band. The built in antenna tuners are not normally known for wide range capability. In any case you will need a balun to go from the balanced line to the unbalanced input of your tuner. Try the balun with your built in tuner and see what it will do. You can also try different lengths of feedline (roll up the excess). You may find your

tuner will get you on a couple of bands. You might also be able to borrow an external tuner in order to see how it will work with the balun.

It all depends what you want in an antenna. Are you interested in DX or talking to the guy in the next town? What bands are you wanting to use the antenna for?

You can easily model your low loop antenna with readily available (free) software. The results will tell you if putting up a (short)low loop will meet your goals.

If you are a DXer you will be disappointed with the performance of a low loop. A vertical would be much better suited for you.

Larry, There are several choices for you.
1. you can make a loop and run the end over the roof instead
of along the eve on the end of the house.
2. You can make the antenna a dipole by running the wire like
a loop and putting an insulator in the center and at the ends.
I would make the ends about 10 feet apart.
3. get permission to install a flag pole and install a vertical like
the Force 12 that looks like a flag pole with coax underground.
Run a small gauge wire (Nr 24 to 30) from the house to the
pole for an endfed wire on 80 and 40.
4. Install a wind vane on one end of house about 5 feet up and a
similar pole at the other end. Run a wire from the shack up to
one pole and across to the other using fine gauge wire and
feed it like a random wire.
5. Install a TV antenna on the far end of the house from your
shack and run the feedline the length of the house above the
roof and feed that as an end fed wire. I understand, IIRC, that
the FCC ruling, while it did not include Amateur antennas it did
prevent the homeowners assn from prohibiting TV antennas.
6. Feed Nr 1 or 2 with ladder line and, Yes, use a balanced line tuner.
7. Feed Nr 1 or 2 with ladder line and a 4 to 1 balun and use your
auto tuner. You may find some freqs where your tuner will not
match since most won't handle over a 3 or 4 to one match.
8. Do like #2 and feed under the eves with a SGC auto tuner, or
similar type, for all bands. I did this at my house in Florida with
a similar situation.
9. Join a gym and do lots of exercise to work off your frustrations.

Healthfully yours,
Don W4BWS

Subject: Re: [SkyWires] Newbie Questions about a Skywire Design That is Low to the Ground

Hi Karl...
Our ham radio club had a guest speaker recently for our version of your
fcc... He gave us a suggestion regarding installing such things as
towers... which made sence to me....
He suggestion was to start out small and simple... Remember ham radio is
going to be, or should be, a life long hobby.. Don't try to put up a huge
antenna right away...
Start out small and simple... Consider putting up a simple random wire

first and let your neighbourhood get used to that first...
The following year, put un a single or two sections of tower but only put up a 2 meter ground plane antenna on it.... possibly you can attach the house end of your random wire antenna to it as well...
In short, avoid putting up large antennas during your first few years as an amateur.. Let your neighbourhood get used to you, as an amateur, slowly....

Subject: [SkyWires] Newbie Questions about a Skywire Design That is Low to the Ground

I'm new to all this and could use some help. What do you think of my plan?

I live in a single storey house in an area where the CC&R's and the city make erecting an antenna difficult. In addition, I have no trees on my property.

What I do have is about 200 ft of perimeter to the house and wooden eves to which a wire antenna could be stapled. The house is not quite square but rectangular, measuring 47 ft x 51 ft.

All of this makes me think a skywire loop may be the way to go except that 200 ft is neither correct for a 40 meter loop (142ft) nor for an 80 meter loop (272ft). It is actually tuned to 5.1 MHz (59 meters) by L=1005/freq. How much of a problem will this be?

I'm thinking of using ladderline so I could access a range of bands. Unfortunately, the house is a single storey so the ladderline will only drop about 8 feet into the window of the shack. How big a problem is that?

I'll be using a Kenwood TS-440 with internal antenna tuner. Don't you think I will need an external one as well?

Thanks in advance for your thoughts.

> Thanks in advance for your thoughts.

Here is something else you should consider. RF Safety. Indeed it is your duty as an amateur licensee to do so.

You antenna as you described will be in close proximity to people in the house. The residents are going to be enclosed by an RF field. Check this out before you do anything. Remember a loop has gain over a dipole. Also the gain changes as you change bands.

http://n5xu.ece.utexas.edu/rfsafety/

If that worked ok for you then another consideration should be RFI. having an RF field this close to your house can cause problems with other electronic devices including your telephone. Are the other (non-ham) occupants willing to put up with this?

I am NOT trying to discourage you. But having done ham operations in similar situations to yours I know some of the pitfalls.

Wow, thanks Erik. I will read and re-read this many times as the days go by and I work on this antenna project. Lot's of valuable stuff!

Thanks Karl,

You are very welcome. I hope you do well with your project and my info helps in some measure. I was serious about posting with your progress. It is always interesting to hear how people run into unanticipated issues and how the original --and sometimes new-- problems are solved!

Say, do you mind if I quote your comment? I have been considering gathering up email's such as this one that I have written over the years and placing them all into a single volume. Having such a heart-felt expression as your would be a nice touch.

If you do agree, please include your call sign in the rely.

In any event, be careful when you're up that ladder and have a ton of fun playing with your radio when it is up and running!

Do recall other people living in the house (if any) once informed of the
RF exposure situation, changes their exposure limits by FCC rules.

Topic: 122 Message: 2729

Hello,

I am constructing a large loop and believe I will have close to 1500' when done.

I am using open wire feeder to a tree that is almost 80 feet high. Right now, the loop is a long dipole, about 700' bent in half a rectangle.

I am trying to make a circle in the woods on my 14 acres. It is slow going because of the density of the woods.

Anyway, the average height will be 65' or so.

Right now, the antenna is excellent, being my best 30M and 40M antenna, and beats the pants off the 40M delta loop at 70'.

I noticed, however, that on 20M and above, the long 'dipole' is much noisier than the 2 ele quad. And the quad beats the pants off the long dipole. Can I expect the noise to diminish when I close the loop?

ALso, I read somewhere that one fellow thought it might be best to add a switching arrangement on the side opposite the feed point to either short or open the other side. What do you all think about that?

2733. Running two separate loops

Yahoo group: SkyWires
Date: 2007-10-24 20:26:13 UTC
From: Callum M0MCX
Topic: 2733 Message: 2733

I have a 40m loop and an 80m loop. Both have 4:1 baluns directly attached to the loops with coax running back to the shack. The feedpoints are within 15 feet of each other.

I'm planning on running short lengths of twin-feeder from each of the feedpoints of the loops to a 12V relay to switch between loops before feeding a high-power balun which will feed a small single coax run to shack.

The benefits will be:

a) A single run of high quality coax, not two and

b) A single expensive balun, not two of the blighters

OK?

Comments?

Provided adequate separation and routing is observed I don't see any glaring problem. The switch itself is so small compared to the wavelength it's impedance bump should not cause a problem. Just make sure it is mechanically and electrically sound. The primary area for potential problems lies in unbalancing the balanced line (ladder line). Keep the coax run as short as is comfortable (it will be the area of greatest loss). Should work just fine.

Callum,

Oh, why do you want two loops? Wouldn't a single larger loop feed with open wire line
be better, having gain on 40M? Perhaps you have an issue with using a tuner, and, if so,
OK.

I am going to use my loop on 80M and up.

Glen,

I've had two "tuned" loops for both 40m and 80m in the back garden for about three years now. The 40m one is slightly inside the 80m one - but they do have separate feeders. Currently, I feed these directly with coax to a balun and I don't want any sort of ATU in line which adds complexity to what is endlessly an experimental antenna (and I run these with high power sometimes so I would have to build something pretty bullet proof if I did).

Switching a few antennas with a relay may give me an interesting dimension.

I assume adding a few feet of twin feeder will hardly change the impedance?

2738. No Room

Yahoo group: SkyWires
Date: 2007-10-28 18:38:43 UTC
From: Paul
Topic: 2738 Message: 2738

What do you do when have no room for a sky wire setup. I really want to put on up, but I don't have the room. I have about 25 feet up and 300 feet total to put an wire up in. Can someone tell me if this enough to put it up, or should try a different way.

2739. Re: Newbie Questions about a Skywire Design That is Low to the Ground - Update

Yahoo group: SkyWires
Date: 2007-10-28 18:47:53 UTC
From: Karl
Topic: 2708 Message: 2739

As promised, here is the update.

So far I've put a #14 coated wire on half of the house's perimeter by stapling it to the eves. The wire is about 3 inches from the gutters, but I've really had no choice. The final antenna will not be planar because at one end of the house I had to go up the pitch of the roof and down the other side to keep the wire hidden as much as possible. I used my fishing rod and it worked great. Pulled a length of twine over the top followed by the wire. That was in the front of the house. In the back I'm planning to just go straight across about ten feet above ground partly because my DISH antenna is on the apex and I don't want to get too close.

I've ordered a 4:1 voltage balun (LDG) for use outside the shack to convert the ladder line to coax before going through the window to the transceiver. I expect to order the ladder line on Monday. The Kenwood TS-440 transceiver arrives this week. It has a built in antenna tuner.

I've also made a wooden "T" shaped insulator to connect the antenna to the ladder line. It will be mounted just above the window to the shack.

Thanks to all for their help and as usual any comments would be appreciated.

Hi Karl,

That sounds like a very reasonable plan.

I'd have a few extra lengths of coax handy by the XCVR, each with a barrel connector (or build a fancy-dancy switching box). If you find you can't tune a given frequency, add a length of coax.

(Say around 1/8-wavelength -- and if that doesn't help, add another -- but don't worry about the 1/8-WL length too much; just change the length of the coax, which in turn alters the complex impedance presented to the output terminal of the XCVR. If you can shift the impedance far enough, you may find your tuner "suddenly starts working" ;) When you have added one full WL you'll be right back where you started.)

You're in better shape than me! J

I just put one up a few months ago and had a lot less room than you. I was only able to put up about 145 feet of wire, just a little over what I needed for 40M. It tunes up well in just about all the bands, 40 and up. I really haven't had a chance to do anything else with it yet. I plan on getting some PSK31 time in within the next couple of weeks, though.

What do you mean "no room"?? :-)

My back yard is 30ft wide by 60ft long.

I had a 150 odd ft loop up at 20ft for about 2 years, it worked gangbusters on 40m upwards.
Hooking a GDO to the system showed a good dip at 6.9MHz or so.
The loop had 15ft of RG58 coax feeder and a 15 turn choke at the feedpoint.
The coax feeder went to an MFJ-949e manual T match tuner and I could get a good match on all bands 160 - 10m

Now I have a bigger sloping loop up, details at
HYPERLINK
"http://homepage.ntlworld.com/paultom/"http://homepage.ntlworld.com/paultom/

Put it up and have fun!

Paul MW0CDO.

2745. My first loop

Yahoo group: SkyWires
Date: 2007-10-29 14:07:51 UTC
From: martin_ehrenfried
Topic: 2745 Message: 2745

Hi All,

I just reworked my antenna to try and obtain better multiband performance.

Originally I had a G5RV at 30' one leg running approx N-S the other E-W.

This weekend I modified it to create a 60m diameter loop (each leg about 15m long) at an average height of 25'

This is fed at one of the corners by a 4:1 balun via the existing 200' length of Heliax and auto tuner in the shack. The tuner and Heliax were previously used with the G5RV.

I was able to use the CQWW contest at the weekend to evaluate the performance on receive and also use a calibrated field strength meter and remote receiver to measure the transmit signal.

The results were disappointing. Apart from a slight improvement on 10m the resulting signals were practically identical to those I can obtain using the G5RV, which is a lot simpler antenna to install.

The other problem is that the loop is closer to the house, so I get more RX noise and TX RF induced into the house wiring and electronics.

My current feeling is that I'm not going to achieve a significant improvement, I should concentrate on getting the G5RV higher up rather than persevere with loops.

Where am I going wrong, or am I expecting too much from the loop ?

Martin - G8JNJ

Martin,

L. B. Cebik, W4RNL, is an authority on loop antennas. See his excellent article at http://www.cebik.com/wire/horloop.html.

The following two charts taken from this article summarize a lot of useful information about large loop antennas. Bottom line: to compete with a dipole, the loop should be a minimum 2-wavelengths at the lowest frequency of operation and preferably 4-wavelengths or more. You must also get your loop up higher to lower the takeoff angle (angle of radiation). If you are serious, you should also model in advance to determine best circumference. Randomly choosing a length is not the best way to get good performance. For ham bands, a 283-foot circumference is a good compromise of length vs. performance on both transmit and receive.

Comparative Performance of a Circular 2-wavelength Loop and a Dipole at Various Heights
Circular Loop Dipole
Height Max. Gain TO Angle Max. Gain TO Angle
wavelengths dBi degrees dBi degrees
2.0 7.36 7 8.05 7
1.0 7.27 14 7.98 14
0.75 7.75 19 7.57 19
0.5 7.43 29 7.91 28
0.25 5.94 47 6.33 60
0.15 4.76 52 6.59 90

Maximum Gain Values for Each Antenna at Each Sampled Frequency
All loops are 2-wavelengths at F.
Frequency F 2F 4F 8F
TO angle (degrees) 14 7 4 2
Antenna
Circle 7.27 9.22 10.71 11.57
Triangle, corner-fed 8.34 9.95 14.38 8.41
Triangle, Side-fed 8.34 10.45 13.24 8.94
Square, side-fed 8.42 11.29 13.59 14.29
Square, corner-fed 6.95 11.51 14.28 14.92
Reference Dipole/Doublet 7.99 9.66 9.64 11.16

I operated the CQ WW SSB contest this past weekend with a 283-foot (1-wavelength @ 4MHz) horizontal delta loop about 80 feet high. On the higher frequencies (14~28MHz) it performs like a beam antenna except having gain in all directions at low takeoff angle and not needing rotation. It is an excellent DX antenna, especially considering the low cost if you have tall trees. Having said that, I'm still working

toward installing a high yagi.

Hi Murray,

Thanks for this,I have spent many hours reading the various articles on the wonderful Cebik website. However I had overlooked the significance of this particular article.

I concur with his conclusions. My loop is too small and too low for effective operation on the lower frequency bands. As predicted in the article my loop does work well on 10m where the diameter is greater than 4 wavelengths, and the height is just under a wavelength above ground.

So it looks like I don't have enough real estate, or high enough support structures to faciliate a useful size loop.

Once again, thanks for pointing me in the right direction.

Few of us of the ideal situation for a theoretically properly
installed loop. Therefore, install the best you can and enjoy what it
can offer. If nothing else, the very low noise I enjoy with the loop
makes it capable of copying weaker signals than my elevated vertical.
I also feel the stability of reception (subjective, I know) makes it
worth the effort of installation.

2750. Another Skywire Newbie with Questions

Yahoo group: SkyWires
Date: 2007-10-31 01:40:34 UTC
From: wb4asz
Topic: 2750 Message: 2750

Hello All,
I am a "longtime listener, first time caller".
After reading many of the posts on this site, I was convinced that the Skywire Loop antenna was my best choice. Read all of Cebik's articles on loops several times. Finally took down the Butternut vertical and was committed to the loop. After drafting the back yard, with tree, I realized that a 160M loop was out of the question, but the 80M would be easy. After getting a new Palstar BT1500A tuner and some W7FG balanced feedline, I went to work gathering parts and 12ga stranded, insulated wire. The tree was only about 40 feet tall and in a poor location to use as a support and it seemed to move a lot in the wind. Therefore, the tree was out. I opted for 2" steel pipe masts, but was afraid to go higher than 20'. The loop seemed to tune fine for stateside contacts, but DX was eluding me. Determined that "height was everything". Will work to raise it up to 40', even if on only one side of the square.

I was really interested in operating the loop on 160M. The idea of shorting the feedline together would be very inconvenient and the feedline is vertical only about 18 feet. Not much for a vertical. I tried placing a loading coil in the opposite side that let the loop load OK, and all bands appeared to load. However, the coil was #22ga emanaled wire on a 3/4" PVC pipe. I was afraid the coil would represent too much power loss on all other bands, so I took it out. Should I just make a comparable coil with larger wire, or just leave it out and be happy with 80-10M?

Has anyone ever tried placing a 160M trap in the opposte side of a fullwave 80M loop to form a halfwave dipole on 160? Do you think is a better solution to the loading coil?

Terry, WB4ASZ

Did you try tuning it on 160 WITHOUT the coil? Some of the
tuners on the market today will tune almost anything almost anywhere.

Yes Earl, I too thought the tuner should be able to tune into the 80M loop, without modifications. I tried to load the antenna with only the tuner. I even lengthened the wire loop by 30', with the same results. VSWR was greater than 5:1 with all possible tuner configurations and settings. I intend to connect the antenna analyzer to the tuner tonight and see what reactance is being seen by the radio. Maybe then I can get an idea as to what it is missing, inductance or capacitance. Logic would say that with a short antenna, the combination of tuner and antenna should still be capacitive and require additional inductance to tune. But we shall see. Thanks for your interest in my problem.

Gee, that's surprising, Terry. My next thought is that you
should probably rewind your coil with larger wire and put it back
in. Only actual on-the-air operating will determine if that gives
you too much loss or not.

I've been wondering about putting some kind of capacity hat
on the END of my long wire to give me a little lower frequency
capability, but haven't tried it yet -- this might be an idea for you
to explore, too.

2759. Yet another Newbie

Yahoo group: SkyWires
Date: 2007-11-09 17:53:53 UTC
From: Tim Folkenson
Topic: 2759 Message: 2759

After plowing through lots of posts and learning just enough to be dangerous, I need to get some specific advice about my weekend antenna project plans. Summary goes like this......

Current rig:

RADIO:1970's Tempo One - 100w output, no protection circuits, no way to reduce power.

Tuner: TenTec 247 - 100w rated with balanced, unbalanced, and longwire inputs

Coax: 75ohm Quad shield, Silicone injected (Underground/Underwater rated) RG-6 (I was a cable guy for many years and had 1000' of the stuff laying around) It performs very well and has very little loss and reads 1.2:1 SWR @50ohms with the analyzer at the TX without the tuner.

Antenna: 40m dipole with extra legs for 20m (I don't call it multiband because it doesn't tune up very well)

Shack: Under the stairs in the far corner of the basement. Coax runs through the joists, up two stories along the chimney, through the attic and out my vent. It then runs up a 16' mast to the dipole. Height is about 50' AGL in front and 65' AGL in back.

Weekend plans:

Before reading about the skywire antenna, I had planned to construct 80m,40m,20m,15m dipoles on the existing mast with a separate feed line for each. They would be spaced about 1/2 meter apart. I nay also mount a remote switch in the attic to avoid running all 6 lines (4 new dipoles plus longwire and 10m dipole in the rafters)

Problem:

If I go with a skywire, I need to use coax to feed to the shack so multiband operation is limited and/or eliminated as an option? Height would be about 50' all around and would be 1 full 80m wavelength. I'd love to use just a loop for everything but it seems that isn't possible?

The other issue is my inability to reduce power with my old rig. Tuning needs to be quick and bad SWR can cause some damage?

The bottom line is how well does a coax fed skywire perform over a well cut mono-band dipole of the same basic height?

Opinions????

> The other issue is my inability to reduce power with my old rig.
> Tuning needs to be quick and bad SWR can cause some damage?

I'll only address this right now because it is the one thing that can sink your boat, so to speak.

You can cause damage transmitting into too high of an swr load. Since you can't slowly increase output power you need to in advance make sure you are close to a low swr (defined as whatever the manufacturer says, perhaps 2:1, perhaps 1.5:1 -- so you need to find that 'safe value').

Therefore, you should get a device that will let you determine the swr before applying power.

#1. Get an analyzer like the MFJ-259/269 or one of the other manufacturers. The idea being you read the impedance before hooking up your XCVR, and adjust it until it is 'good enough' to be safe. The 269 at least can also be changed to work with a 75-Ohm input impedance. (I've never tried this but I recall reading that in the manual.)

(As a side note, the theoretical swr of going from 50 to 75 Ohms (purely resistive; e.g. no reactance present) should be 1.5:1, not 1.2:1. This isn't a great deal of difference, especially given the typical margin of error in amateur radio equipment. Perhaps the other extra loss is in the line, if it isn't a meter error, running from the chimney to the basement.)

#2. Ten-Tec makes a kit that can be used to "tune your tuner" (I think that is the line they used.) It compares the impedance seen in the device to a small on-board resistor. In my case I set it close to 50-52-Ohms and when this matches the transmission line connected to it, it does something.... "what" exactly I don't recall. Makes a noise or a LED goes on (I think the tone changes -- I could be wrong on the specific "that's close" indicator).

#3. Use a second low-power transmitter to inject RF at the frequency you're fixing to transmit on with the 100-w rig and use a swr meter to verify the swr is within safe limits.

Have fun!

From: Tim Folkenson
Topic: 2759 Message: 2761

Thanks to all that have emailed me offline and posted here. It's been
a great help.

I do have a MFJ on loan and can check things out before I hook it up.

I also have a QRP FT301 with a drive control to hook up if the MFJ
says it's ok.

My biggest question that still remains regarding a coax feed vs
Ladder line. Is a coax fed skywire a multiband antenna?

I keep thinking about how I could feed this thing properly but it's
just not in the cards until I remodel the basement.

Should I keep this project on hold and go back to my dipoles until my
layout improves?

Thanks again everyone.

Attachments: 1 described; binary payloads are missing from this source WARC

This might be an option worth
considering.

When we had to tune some manual tap
loading networks a few decades ago we
would to the following.We would take and
insert a T connecton at any convienent
point between the transmitter and the
Manual
matching network.

We would then first add a dummy load to
the tee connector and disconnect the
matching network and tune the
transmitter to the dummy load. Let's
say the antenna starts off looking like
5,000 ohms which it wont. T-ing our out
put if we take the product over the sum
or our dummy load impedance and our bad
mismatched impedance ie. 50*5000 or
250,000 ohms divided by 50+5000 or 5050
we get the following 25000/5050= 49.50
ohms at the transmitter. Not Bad... 50
ohm load and 2000 ohm mismatch before
tuning would yeild 48.78 ohms at the
transmitter.... 1,000,000 ohms of
impedance across the 50 ohm will give
you approximately 50 ohms

Then we would the install a SWR Bridge
to the connector and then connect the
tuner to bridge. { This would basically
limit the SWR to an acceptable level at
the transmitter. We then could adjust
the tuner manually for a minimum SWR.
Once you get to a 1 to 1 SWR at the
transmitter will see a 25 ohm Load or
an SWR or 2.0 to 1. That won't hurt
your rig.Now Once that is achieved you
can then just disconnect the dummy load
and your ready to go. 50 ohms appearing
at the transmitter output.

In other words, if you tee your output
and no matter how high the impedance is

the transmitter will see something extremely close to 50 ohms.When you tune your tuner and get your match you have 50*50/100 or 2500/100=25ohms.

Simple and cheap, and very safe on your equipment

OK, Tim, we'll assume the not-blowing-up the radio is covered ;) heheheh....

Apparently the 'best' answer is to go ahead and remodel that basement!
Heheh, will your wife belief you're doing it for her? Maybe you both
get a hobby room with a sliding window between!? ;) ....anyway....

Transmission Line Woes

The transmission line you use to feed your antenna doesn't matter in
and of itself, nor does it matter what kind of antenna is at the far
end, other than envelope, take of angle, and that sort of thing.

Balance matters when using balanced line (route that ladder line along
a piece of metal or too close to an electrical line and each side of
the ladder line no longer cancels the other side -- they become an
antenna element), and keeping the RF inside coax matters (RF on the
outside of the shielding also act as an antenna, not as feed line).

Once you meet the above goals, the loss inherent in the line matters
(attenuation). Higher impedance line has less transmission loss. Hard
coax line and balanced wire transmission line both have very low
attenuation losses, I suppose because air is the dielectric in both
cases. But with other kinds of coax, the line attenuations adds up
much more rapidly.

But you might explore some of the "poor man's hard line" which are
supposed to be very low loss coax.

Since you are routing through and along so many things (basement,
floors, roof, chimney, etc) you really do need either coax or shielded
balanced line. I've never priced shielded balanced line, but you may
want to look into that as a 3rd option.

Antenna Type (Loop vs. Dipole)

Dipoles change their polarization due to physical orientation. Loops
can change their polarization either by physical orientation or by
where the feed point is connected. This may or may not be an advantage

for your use.

Both dipoles and loops can be multi-banded. Really, pretty much anything that conducts RF *can* be, but you'll have a multitude of propagation envelopes, and levels of impedance/reactance/swr to consider. Some will be useful and some not so much.

Most likely you have already considered these points and decided to try a loop.

Practical Transmission Line Options

As mentioned above, you really need some kind of shielded line. This is because you are so close to so many things. There are at least three options to explore: (1) hard line; (2) shielded coax of the "low loss" variety; and (3) shielded balanced line.

If you can model the antenna you will be able to get an idea of what feed point impedances to expect. This may help you decide specifically what transmission line would be best. Failing that, go with whatever has the lowest attenuation loss. This data should be readily available from the manufacturer. Typically they pick one or frequencies and state the amount of loss over some number of feet. Find the frequencies close to yours, 10-meters has the greatest loss in HF, and adjust the length to match yours. The feet/length conversion should be simple math. If they tell you the loss for 100-feet and you're using 200-feet, double the loss, etc.

Attenuation

All line has loss. Electrons cause friction moving from one point to another, and there is also dielectric loss. Air is a really good insulator with very little dielectric loss, which is why we enjoy such low losses from hard line and balanced line. As you fill the space between the two wires (either balanced line or between the center conductor and the inside surface of the shield on coax) with stuff other than air, dielectric loss increases.

Also to be considered is how much you expect to bang the line around and what the environment will be. In this case the outdoor portions will be subjected to UV from the sunlight. The rest is indoors and other than laying against things and dealing with electrical sources inside, it is pretty much protected from the environment by the house itself. In any case, you should attempt to route your transmission line away from things: fans, electrical lines, etc.

SWR

Now, when the RF gets to the point that connects to the antenna, less whatever energy was lost in the transmission line along the way (attenuation), some will get into the antenna and some will reflect off, and head back toward the XCVR.

That which enters the antenna we need not be concerned about, as it'll radiate as we wish it to (most of it anyway). The part that isn't "absorbed by the load" (the antenna) will travel back to the XCVR (or transmatch if used), less the attenuation (for a second time). When it encounters the XCVR or transmatch, it'll re-reflect and head back toward the antenna along with however much additional RF the XCVR has added. Again, less attenuation losses (the new forward wave taking the loss once, and the re-reflected portion of the wave taking loss for the third time -- the higher the swr, the more often the waves reflect back and forth before escaping to the antenna, and therefore, the greater the attenuation losses).

Comparing the forward wave to the reflected wave gives the swr.

Comparing the transmission line impedance to that of the antenna feed point will give you an idea of how much RF is absorbed by the antenna and how much is reflected off it each time a forward wave reaches it (that forward wave being comprised of both the re-reflected and new RF). When the antenna feed point is the same impedance as the transmission line 100% goes into the antenna. That results in a 1:1 swr. Realistically, anything 1.5:1 down to 1:1 is perfectly acceptable for our uses. If there is very little attenuation in the line, this swr can be considerably higher without there being much effective difference to our use.

Reactance

Reactance is resistance to current in an ac circuit (like RF). It is basically energy caught in a circle that does nothing productive for us. If capacitive reactance, it is caught in an electrical field and if inductive reactance, it is caught in a magnetic field. Either way, it is stored in one portion of the ac cycle and returned to the system in the next alternate portion of the cycle. Net result to us is no work done.

Impedance Matching

If we add the opposite kind of reactance to the system and in the same magnitude (but opposite sign: capacitive is negative and inductive is positive) we eliminate the reactance. What is left is purely resistive. Now if we can match this purely resistive part to our XCVR (typically around 50-Ohms theses days) it will fully load into (transmit into) the transmission line, and do so safely.

(The same principals apply to reception, but that won't damage our equipment, so we usually only talk about transmitting.)

This allows us to generate maximum power.

Now if the antenna feed point and transmission line have the same impedance 100% of this power is radiated (or nearly 100% -- nothing is perfect, so there is always a tiny loss).

If the antenna feed point and transmission line have a different impedance some RF bounces back and forth. If the attenuation is low, that doesn't negatively affect our ultimate antenna radiation. That RF which isn't lost to attenuation will will eventually radiate from the antenna.

So there you have it!

Eliminate the reactance, properly match the XCVR to the transmission line it is connected to (directly or through a transmatch (aka "tuner")) and if the far end of the transmission line is very different than the antenna feed point impedance, use low loss line. The less attenuation loss the better, and especially when experiencing high swr on the line.

How many bands will you get?

This depends upon the impedance matching range of your transmatch. Lower impedance is more difficult to match than higher impedance. How high and how low of a match you can find is dependent upon the components. Manufacturer's should be able to provide you with their data. Compare this to you antenna's upper and lower limits and you'll find how many bands you can match.

It is certainly possible to have very low loss in the transmatch components at certain frequencies and higher loss at other frequencies. Again, the manufacturer should be able to provide this information. Or you can put a RF power meter on either side of the transmatch and judge for yourself if there is "too much" loss, and if so, where.

Will these be useful bands?

This depends on all of the above and more. Propagation for one. Envelope, take off angle, etc. How much power was lost vs. how much power eventually radiates from the antenna. My guess is if you can talk to most people you hear, and work some really cool DX it is "fine" ;)

Hope that helps!

2764. balanced line swr meter

Yahoo group: SkyWires
Date: 2007-11-10 03:56:14 UTC
From: rudywhoizme
Topic: 2764 Message: 2764

I recently acquired an MC Jones MicroMatch model MM-1 while prowling around a Phoenix antique shop. It appears to be a balanced line swr meter. I haven't discovered much about it except that it was advertised for sale in the late 40's. I would appreciate any further information, or leads to a manual.

Tim-

I used an 80M full wave loop for about 5 years, fed with RG-58 Coax. It performed way above my wildest expectations. I recently changed to commercial window line feed, and it is a bit better, maybe, but not by orders of magnitude. Use your Coax, an get on the air with it!

To "tune" your antenna tuner, buy a Palomar R_X impedance bridge (Reasonable on Ebay), and learn how to use it. You can use it to adjust your tuner, and you may actually learn a bunch about antennas and feed lines while you are at it!! Older Handbooks have some good info on using one. Keep the $$ you save on the "analyzer" to improve other areas of your shack/antenna/equipment, etc.

Ask 10 guys from your local club what exactly they use their $300+ MFJ analyzers for, and my guess (and experience) is that 9 out of 10 have only ever used it to find out the SWR on their antenna system.

Just my experiences, and I guess yours could be different.

Best luck any way you go.

Karl, It does not sound like you have many options. I think that you will be surprised at how well it will work in spite of all the "compromises". The ladder line with the external balun is definately the way to go since you will be using an odd length antenna. While you will probably not crush any pilepus, you will work you share of stations. You may find that digital modes such as BPSK (psk 31) or CW will probably net you your best results. Not to say that SSB will not be possible but you will want to keep the power down due to the antenna having total and direct contact with your house, not to mention RF exposure and TVI. Good luck.

Steve

Karl <kmgeneral@...> wrote:
As promised, here is the update.

So far I've put a #14 coated wire on half of the house's perimeter by stapling it to the eves. The wire is about 3 inches from the gutters, but I've really had no choice. The final antenna will not be planar because at one end of the house I had to go up the pitch of the roof and down the other side to keep the wire hidden as much as possible. I used my fishing rod and it worked great. Pulled a length of twine over the top followed by the wire. That was in the front of the house. In the back I'm planning to just go straight across about ten feet above ground partly because my DISH antenna is on the apex and I don't want to get too close.

I've ordered a 4:1 voltage balun (LDG) for use outside the shack to convert the ladder line to coax before going through the window to the transceiver. I expect to order the ladder line on Monday. The Kenwood TS-440 transceiver arrives this week. It has a built in antenna tuner.

I've also made a wooden "T" shaped insulator to connect the antenna to the ladder line. It will be mounted just above the window to the shack.

Thanks to all for their help and as usual any comments would be appreciated.

2767. Question about open loop in attic

Yahoo group: SkyWires
Date: 2007-11-11 20:10:03 UTC
From: Jonathan Helis KB5IAV
Topic: 2767 Message: 2767

I don't have alot of outdoor space for an antenna so I've been forced to put an antenna in the attic. I built an open loop antenna, basically a dipole bent into a rectangle. It's 25ft x 5ft, for a total of 60 feet. It's fed at one corner with 300ohm twinlead and the opposite corner is open.

I'm running the twinlead through an MFJ 911H balun which can work at either 1:1 or 4:1 at the flip of a switch. I tested it using an MFJ-259 antenna analyzer and when using a 1:1 ratio, the lowest frequency with an acceptable SWR without a tuner is 21.320 mhz. I thought the antenna would be at a low SWR at a frequency lower than that. At 4:1, the lowest frequency with acceptable SWR is 38.063 mhz.

I've tried loading on other frequencies with a homebrew transmatch but haven't had any luck doing so. On a positive note, seems this antenna and balun combo can produce very low SWR on most of 6 and 2 meters.

I was considering converting it to a closed loop by attaching the wires at the corner, but am not sure yet. If anyone has any suggestions on what to do, please drop me a line.

Thank you.

Jonathan,
You might try inserting an inductor across the open corner of the rectangular bent dipole. You could wind several feet (the more the better, up to a point) of wire on a piece of pvc pipe, broom handle, or dowel rod etc..
Good Luck, Ace

Jonathan, Why dont you look at making a DCTL loop. (Google it) They
are small and can be hung up anywhere . My DCTL for 40 meters sits
on a chair in my shack and outperforms a G5RV dipole at 40 ft.
You must have a variable capacitor to tune it as it is quite sharp
in resonance.
Try it you will enjoy it

i am satyan sarth - vu3mes from india. i plan to build a rectangular wire loop antenna with multi-band operation in mind. i will be using a 144feet insulated wire with 7.000khz as the lowest frequency for opeation. i have collected lot of details on wire loops from websites like L.B Cebiks and radioworks.com. some people say i must use ladder line type open wire feeder while other say i can use standard 50 or 75 ohm co-axial feeder. i will be using this antenna with a yaesu foxtango 101-e primarly, though i also have an icom ic-718. my question is

1. can i use the standard 50/75 ohm co-axial feeder line along with a diamond bu-55 centre balun to feed this antanne system?

2. secondly will it be possible to use this antenna without an antenna tuner and only using the ft-101e's tuning and loading system for operating in 40/20/15 mtrs?

replies from the experienced friends in this forum will be highly appreciated.

Hi, Satyan:

I am not as experienced as some, but everything I've
heard tells me that ladder line will let you
effectively tune an antenna for different bands with
the appropriate tuner.

Satyan

I have the same antenna. I use Low Loss coax to a 4:1 balun. I achieve good SWR (and radiation) on 40m and 20m. It *does* work also on 15m and 10m too but I rarely go there.

The 4:1 balun is more important for the 20m band because the impedance goes higher here, to about 250 ohms I seem to remember.

With your FT101 and without an ATU, you will get good results even at just 20 feet height - change the height and the impedance (and my properties discussed above) will change. What height did you think of installing this?

If you have a good tuner, you could probably get it to load anywhere using coax, but when dealing with high SWR on your feedline, the coax will have alot more loss than a balanced line such as ladder line, twinlead, etc. If you plan to use it for multiple band operation, balanced line is a much better option.

Topic: 2770 Message: 2776

I believe the ferret would have distorted the directionality of the cage's radiation pattern. There is evidence that a trained animal could permit the operator to "rotate the beam" by directing the ferret to different parts of the cage.

This field of inquiry is in its infancy and if anyone is interested in researching it further I can sell them a ferret cage in mink condition.

2777. ladder line

Yahoo group: SkyWires
Date: 2007-11-27 23:52:07 UTC
From: cesar maligalig
Topic: 2777 Message: 2777

Satyan,

I have a full-wave delta loop (triangle) which is tuned on 7.045 - which is the calling frequency here in Philippines for amateurs. It is tied to three coconuts trees via pulleys so it is very easy to lower for maintenance if ever. I used it on 40 m and 15 m, no need to tune on 15m - because it is a perfect harmonic of 40m. I tuned the loop by cutting slowly until it was 1.2:1 on the swr meter. I use only the auto tuner on my ft920, with no problems.

The length of 1 side of my delta loop is 14.1 meters and I used an rg59 cable cut to 23 ft. as my transformer - to lower the antenna impedance to 50ohms which is what our modern radios now is set to. Then it is attached to rg8 cable which goes to my radio. I didn't use ladder line, because what we have here locally are not very good quality, they crack easily.

There are a lot of technical people here in this egroup that can explain to you the mathematics behind the length of my transformer (balun). That is my experience and I am very satisfied with my skywire. 73

Hi Steve,

Yes, you are correct. When a dipole antenna is cut to a half wavelength at a particular frequency .... eg 80 mtrs ... it will represent a resistive impedance of approximately 75 ohms at that frequency. It will then be easily fed with a coax cable and represent a very good match to the cable and to the transceiver. However, if you wish to use the same antenna on other bands ... eg 40 - 10 mtrs ... then you will have to get rid of the coax feed line and substitute a low loss balanced feed line like 300 ohm tv twinlead or 450 ohm ladder line.

The reason is that the antenna will represent a variety of different impedances at the feed point and the coax feed line will represent too great a power loss. The parallel line can deal with high SWR with small power loss making a multi-band antenna possible. The actual impedance at the end of the feed line will depend on the impedance at the feed point (at the particular frequency) and the length of the feed line. Most antenna tuners have a limited range of impedances with which they can deal. So in the construction of the antenna/feed line ... one is often faced with choosing bands and feed line lengths. Adding or subtracting feed line will bring the antenna/feedline into the range of your tuner on the frequencies you are interested in. Nothing is perfect ... everything is a compromise.

Jim, VE3CI

>Steve
>WA1ZFY

Hi Steve,

Well making parallel open wire feed line with duct tape is certainly doing it the hard way hi hi ... But I have no doubt it would be very efficient. I must confess I have constructed my own feed line in the old days using pieces of plastic rod. Time consuming but works very well.

However, I have never used a ferret cage as an antenna or part of an antenna hi hi ... although I am fond of ferrets ... One of my dog's best friends is a ferret hi hi ..

Satyan

I have the same antenna. I use Low Loss coax to a 4:1 balun. I achieve good SWR (and radiation) on 40m and 20m. It *does* work also on 15m and 10m too but I rarely go there.

The 4:1 balun is more important for the 20m band because the impedance goes higher here, to about 250 ohms I seem to remember.

With your FT101 and without an ATU, you will get good results even at just 20 feet height - change the height and the impedance (and my properties discussed above) will change. What height did you think of installing this?

i am satyan sarth - vu3mes from india. i plan to build a rectangular wire loop antenna with multi-band operation in mind. i will be using a 144feet insulated wire with 7.000khz as the lowest frequency for opeation. i have collected lot of details on wire loops from websites like L.B Cebiks and radioworks.com. some people say i must use ladder line type open wire feeder while other say i can use standard 50 or 75 ohm co-axial feeder. i will be using this antenna with a yaesu foxtango 101-e primarly, though i also have an icom ic-718. my

question is

1. can i use the standard 50/75 ohm co-axial feeder line along with a diamond bu-55 centre balun to feed this antanne system?

2. secondly will it be possible to use this antenna without an antenna tuner and only using the ft-101e's tuning and loading system for operating in 40/20/15 mtrs?

replies from the experienced friends in this forum will be highly appreciated.

Satyan,

The bu-55 looks like a 1:1 balun - and only 500 watts. You need to look at a 4:1 version and higher power.

But wait! Please build your antenna with the bu-55 first with low power and measure the SWR and impedance and see what will happen. Being higher off the ground may mean you have a lower impedance than mine.

OK?

2786. Square or rectangular

Yahoo group: SkyWires
Date: 2007-12-22 10:29:43 UTC
From: dxnature
Topic: 2786 Message: 2786

Hi,

Yesterday I looked at the possibilty to mount a 80 meter loop. Since the size of my garden will allow me to go for a horizontal rectangular loop. Is it possible to go rectangular at 28 by 12 meters. I suspect a difference in radiation angle against a square version, but could there be other anomalities to expect?

I will feed the loop with a 450 Ohm ladder and a SG-239 antenna coupler as is do right now with my 40 meter horizontal delta loop. As I cruze daily over the tropical BC bands I hopefully get a better result with the 80 meter loop in play and can use it on the ham bands as well.

All comments are more than welcome.

73's and seasonal greetings,

Ron Liekens
ON3RON - DXA64

Ron,

You left out key pieces of information: how high will the loop be;
where on the loop will you connect the ladder line; on which bands
will you transmit using the loop?

The books say that as the antenna gets rectangular rather than square,
the loop will take on characteristics of a folded dipole rather than a
loop antenna.

Ron,

You'll get the greatest overall performance from a loop antenna by enclosing the greatest amount of area possible (given a constant antenna height). The winning shape would be the circle, but that is almost impossible to implement (requiring an infinite number of supports). The key word here is 'overall'.

Regarding square vs. rectangle, for a given diameter, the square will provide the greatest enclosed area. The more a rectangle deviates from a perfect square, the less area is enclosed.

The shape of the horizontal pattern will also be affected (sq vs rectangle), but this could be beneficial for a given deployment, depending on what pattern you're looking for.

Anyway, just my 2 cents.

From: Christopher Zeman
Topic: 2786 Message: 2791

My loop is a triangle, and varies in height (~27 to ~31 feet). I was going to go with a rectangle, but I wasn't able to get a support rope where I needed it. I have Andrews LDF4-50A (1/4" hardline) running from my shack to the attic where I have a 4:1 balun feeding ~37 feet of 450 window line that leaves the attic through the roof and straight up to the feedpoint. Perhaps the hardline is overkill, but it was free and I had it sitting here.

I've only used it for PSK31 so far, and not very much yet. The reports I have gotten, though, have been great! :) The best part is I don't interfere with ANYTHING in my home, and the neighbors who CAN see the window line haven't said a word. Then again, I've only operated on a casual basis (not very much).

The point is that the loop is a great idea, and you should put up what you can. I think you'll be pleasantly surprised by the results.

Good luck!

Topic: 2786 Message: 2792

I also have a triangular (delta) full-size 80m loop fed with ladder line. It is between 80 and 90 feet high.

I chose triangular because only three skyhooks are needed and also because modeling indicates the triangle shape produces a more desirable pattern on ALL bands from 80m to 10m. The antenna loads well on all bands and works as a DX antenna in most directions. Highly recommended if installed HIGH. Low height also works, but high is best.

Height is definitely key. I'm still determined to get my loop up higher. I'm currently using one oak tree, another tree (I don't know what kind) and the TV antenna mast on my roof. My fourth support would have been another tree, but I may still be able to use it. I have to be cautious how I go about getting my supports up into the trees. There are power lines running along my back and side property lines. The oak tree is at the corner near one pole; the other tree is about 35' south of it along the power lines as well. I could definitely get the supports up higher, but I have to be a little creative and careful. The oak tree is at least 75 - 100 feet tall. My support is around 30 feet up the tree. The other tree is probably at least 30 feet tall, though my support is not quite that high. My antenna is at its lower point in this tree. I'd like to move the support from my roof to the tree I wasn't able to use. That tree is at least 40 or 50 feet tall.

I waited until my neighbors were on vacation to install the antenna. :) Actually, I realized they were on vacation and realized it was the perfect time to do it. We also had company that day so I had to try and balance both. I have time to plan on how to get higher. I'm hoping to find a way to, perhaps, squeeze and 80 meter loop on my property. :)

I also have a triangular (delta) full-size 80m loop fed with ladder line. It is between 80 and 90 feet high.

I chose triangular because only three skyhooks are needed and also because modeling indicates the triangle shape produces a more desirable pattern on ALL bands from 80m to 10m. The antenna loads well on all bands and works as a DX antenna in most directions. Highly recommended if installed HIGH. Low height also works, but high is best.

Has anyone ever tried an hexagonal loop hung within a triangle (i.e. Using 3 supports, and with every other side of the hexagon running along a nonconductive support that supports two adjacent corners of the hexagon?)

Dave,

I suspect this idea is overly complicating the situation. I doubt it would radiate/ receive any better than a conventional square or possibly even a triangle. Put your effort into getting whatever shape you use higher to lower the radiation angle.

Any shape loop will work - octagon, pentagon, etc. The larger the area or aperture inside the loop the better, A circle has the largest area but is impractical. A circle has 1dbd gain over a square. Most people use a square but if you only have 3 supports you can shape it like a triangle. Triangle loops are called Delta loops. A square loop has 1dbd gain over an equal lateral triangle loop. If you use a triangle shape try to make each leg an equal length as this gives the largest inside aperture or area.

If you are a DXer put the loop as high as possible. If you are a local rag chewer like me put the loop any convenient height.
73 and Merry Christmas to all.

Topic: 2798 Message: 2798

Well Guys I finally got by loop up in the back patch. It is a 160m full wave loop at approximately 28 to 30 ft. I have it supported on 5 PVC Conduits telescoped to give me the 28Ft. the PVC is on Steel T-post driven in at about 10 degrees from vertical leaning away from the center of the loop. I threaded the ant. wire through the insulators and pulled it taught with a pully and halyard system on the 6th pole which is a drill Stem pipe with a 10ft. PVC above the steel. got it up in late Oct. and have made a few contacts It is quieter than the Dipole I had up previously. With the holidays I have a new Microphone for my IC 718 so I should be up and making contacts full time soon.

Ace,

What are your thoughts on a full wave length 80 meter (287 feet
circumference) vertical triangle with a flat on top, with an SGC-230
at the feed point which would be at the point on the bottom of the triangle?

73,

Paul

Did you have to back-guy it at the top of every pole to keep it from leaning in ? Also what size of wire did you use ? Curious because of the weight , sounds like you have the makings of a gangbuster all band antenna .

I used this antenna this year with exception of apex up and no SGC-230. Ladder line to apex for feed. My comment is: the higher you raise the lowest point (approaching horizontal instead of vertical loop), the happier you will be if your purpose is distant communication. Taking the low side of the triangle from 10 feet high to 80 feet high opened the world. I suspect even taking the low point up to 30 or 40 feet would help a lot.

Paul,
No doubt it will work to some degree; but I doubt if you can get the bottom feed point high enough to make it really shine. It is well worth trying if you don't have enough room or supports for a horizontally oriented loop antenna.
The larger the area or aperture inside the loop the better.
If you use a triangle shape try to make each leg an equal length as this gives the largest inside aperture or area.

No I did not back guy it, I drove the steel T-Post in the ground at about an 80 degree angle away from the center of the antenna. then I lifted the PVC up and slid it down over the T-Post and the limber PVC would lean away from the center. Before I lifted the PVC up I strung baling twine through the insulators so I could pull the ant. wire through them. The wire is enamel coated about 14ga solid used in winding transformers and I was able to get a stub end of a roll from the plant owner, It stretches some but not bad.

I counted on the flexibility of the PVC to bend and when the wire is pulled taught the PVC bends inside like a bow and puts tension on the wire keeping it tight. as of now we have had no ice but I would expect that Icing conditions would pull the wire and the PVC down a lot. fortunately icing is rare here and what we do have is not long or bad in most years.

PVC does get brittle with cold weather so I will consider this first antenna to be a prototype and I will see how the PVC poles survive the winter. I have about $20 in each PVC pole except the feed point pole. that pole is Drill Stem and PVC, this cost me about $50 so I really don't want to put more of them if I don't have to. I can already see that if it survives the winter I will be fine tuning some of the post locations as the T-Post could have been placed further from the center to provide more tension and support to the wire.

If any one is interested I can attempt to take some photos and post them to the photos section.

2812. "Huff Duff" antenna

Yahoo group: SkyWires
Date: 2007-12-29 20:10:18 UTC
From: knyuen88
Topic: 2812 Message: 2812

What is the ww2 shipboard HFDF antenna("Huff Duff"). The picture
shown it is composed of implicated triangles mounted on top of the
ship's mast rather than a typical DF loop. Their physical sizes are
definately much shorter than the designated reception HF wavelengths.
How it works?
Thanks in advance.

2813. Hi_Fi receiver antenna impedance.

Yahoo group: SkyWires
Date: 2008-01-03 21:40:57 UTC
From: knyuen88
Topic: 2813 Message: 2813

What is the impedance of a Hi Fi receiver AM external antenna input?
Am thinking to connect an longwire outdoor antenna for MW broadcasting
DX.

Noted the set came with a loop antenna to be connected to the ext. AM
Ant. terminals. --- to make it more precise --- a 6 inches dia. coil
with 12 turns of hookup wires.
Thanks in advance.

2814. Loop Photos are Up!!

Yahoo group: SkyWires
Date: 2008-01-04 13:30:06 UTC
From: Steve Holman
Topic: 2814 Message: 2814

Well I was finally able to get time to take photos and post them to the board. I have 5 photos posted that show my version of a Sky Wire Loop.

It is difficult to see the wire in the photos but you should be able to see the supports and how they are used. I already have plans to move some of the supports out from the center as there is slack in the wire in spots of the loop. But that will happen with warmer weather. The wire is free floating in all of the insulators except for the feed point. I can take photos of them and the feed point if anyone wants to see them.

Over Time I am planning to circle the complete back patch with a loop supported by poles like the Feed Point Support. This loop would be close to 1800ft long and would have 5 supports and I would be able to pull more tension on the wire.

2815. Half Wave Open Loop in Attic question

Yahoo group: SkyWires
Date: 2008-01-05 02:55:21 UTC
From: Jonathan Helis KB5IAV
Topic: 2815 Message: 2815

I'm in an area where outdoor antennas wouldn't be easy to put up so for now, I'm working with a half wave open loop antenna in my attic. It's basically a 60 foot long dipole bent into a 25x5 rectangle. Not the best setup I know, but for now I'll have to do.

I have it fed with 300ohm indoor/outdoor foam filled TV twinlead from Radio Shack. I had a big roll of it lying around and decided to use it since I will run this antenna on multiple bands.

I'm loading it up using a LDG Z11 Pro autotuner. I tried a tuner from MFJ, but the inductor fried the first week I had it so I sent it back. The balun I'm using is MFJ 911H, which can be switched between being a 1:1 and a 4:1 balun. I run it at 4:1 and it can load on every band 40-10 meters, and I was able to get it to load on a 60 meter channel.

When operating 20 meter phone, my rig cuts out even though I have a flat SWR. The rig just seems to shut down and not be able to transmit, almost as if the SWR is too high. Sometimes lowering the power helps. What could be causing this problem? Should my twinlead be a different length or should I use the balun as a 1:1? It's nice to be able to get on the air again, but this problem makes working 20 very difficult.

Any help is appreciated.

Thank you.

Jonathan,
My first thought was the power supply might be going south on you, my logic is, as you say the SWR if flat so you radio can transmit at full power, IF your power supply is starting to go on you, or your connections are getting loose, you might not be able to get all of the power your radio needs. But it is just a guess. I hope you find the problem.

Hi Jonathan.

RF getting back into the radio?

Prove by turning down the RF output power.

If turning down the power helps, connect a half wave (about 17 feet on 20m) of insulated wire to the ground terminal of the ATU.

The wire can be laid on the floor under carpet or whatever.

Don’t forget to insulate the end of the wire, high voltages can appear on it.

Some radios are much more immune to RF in the shack than others.

Cheers!

Paul.

Hi Jonathon,

It seems you have the antenna/feed system pretty much under control... I wouldn't worry about the TV twinlead ... I have used it many times with power up to 300 watts. My only suggestion is to try the antenna as a full loop ... e.g. 60' loop. It should be easy to try it ... just connect the ends together. You can easily undo it if it is less effective ... I have used smaller loops like that and found them decent antennas.

As far as the rig cutting out I don't think it is the fault of the antenna ... if your SWR is low the problem is something else. I recall when using my Kenwood TS-50 with an under rated power supply it would cut out on high

power (the TS-50 has 3 levels high at 100w, medium at 50w, and low at 10w). However it worked quite well on medium and low. When I connected it to a robust power supply e.g. the MFJ -1035, rated at 35amps, the rig operated flawlessly.

2820. K9QLL Loop SWR Scans

Yahoo group: SkyWires
Date: 2008-01-05 21:00:16 UTC
From: wv6bwf
Topic: 2820 Message: 2820

I couldn't find real world SWR scans on the net so had to DIY.
Thanks to WB9ROC and the AIM 4170 analyzer.
The scans are for 50 Ohms through the Balun and 450 Ohms direct to
Ladderline. Dotted blue line on graph is 1 to 1 SWR.
I hope this may be of some help to others.
My loop is, I believe, a "typical" 160 meter horizontal loop.

Sorry Jonathan, I got the math wrong.

You need a quarter wave length of wire, not half wave.

17 feet is in the ballpark.

Cheers!

Paul.

From: Dean L.
Topic: 2822 Message: 2825

Have you thought of placing a 2 to 3 ft. standoff
horizontal in the middle of your pole on the back side.
Then run a cable with a turn buckle from top to bottom.
This will give you a back guy with little space taken up.
Place a little force on the guy with the turn buckle and
it will hold a lot of antenna weight.

Hi,

This is the same material I used, but in thicker gauge.

Unfortunately actual specifications seem to be difficult to obtain.

What is the DC resistance of your loop ?

Do you know the weight of the wire per 100' (or similar) ?

My support at one corner has to be a 40' self supporting pole, but
because it's at the corner of the lot, I can't guy it at the opposite
side to take up some of the lateral force. So the weight of wire is
an important consideration for me.

From: KI4BUN / AAV4TP
Topic: 2822 Message: 2831

I had an 80 meter loop up which worked just fine and it was 18 gauge copper stranded 'chandelier wire'. I picked up a 500' roll at Home Depot for about $30.00. I'm sure it's gone up with the insane metals prices these days, but it held up for over 2 years.

My mast poles were each set up just like flagpoles with a pulley, lanyard system, and lanyard cleats. I just clipped the insulators to the lanyards and hoisted the corners of the loop. Worked pretty slick and one could adjust the height of each corner individually to experiment with radiation patterns.

I was running an old Kenwood TS830s and a cheap MFJ tuner and the loop was fed with coax. At the feed-point, I used a 4" x 6" piece of PVC pipe would with 8 turns of coax for a balun/choke. Worked great.

Now I have purchased a house in Ft Worth TX and am anxious to put up another loop down here! I'm really tired of only being able to work mobile. The 18 gauge chandelier wire is what I'll be using for the new antenna.

From: Jim Stafford W4QO
Topic: 2822 Message: 2832

I've been using 16 gauge stranded PVC covered wire for about 15 years on my loop. It has never broken and in last 3.5 years I have 137 countries worked QRP. It is very light weight and the resistance is maybe 3 ohms. It is also very stealthy. I used the GREEN colored PVC. It has never broken although the 1/8" dacron and nylon has broken a couple times. Simple to shoot it back up and pull over the trees. I feed it with 300 Open Wire feeder (about 50') and then go to Coax (25') to come into the house. I have tried it with and without a 1:1 balun - no difference. Takes a tuner of course. Mine is an 80M loop about 70' on a side (280 feet total). It is very hot on 20M.

70 Meters of 26 gauge wire should have 9 ohms. Not sure why your loop has such high resistance IF it is copper plated clad steel.

2833. 160m 1/2 wave Dipole help Needed

Yahoo group: SkyWires
Date: 2008-01-09 23:30:54 UTC
From: k5hsv
Topic: 2833 Message: 2833

According to my antenna analizer on 1.900MHz my SWR is 3.4:1 but origionally it was pretty flat 1:1 before a coax re-routing.

I've re-routed my coax underground from a tower I added a few months back. I'm sending every thing back into the shack by a DX-Engineering CC8 coax box / switch. Now that I've added about 150' of BuryFlex from the shack to the tower and switch box, my home made 160meter dipole, which was cut and tuned to be flat 1:1 SWR on 1.900MHZ, NOW has a 3.4 SWR at the same frequency.

Today I lowered the apex and took a look at the center connection and everything was Ok at that junction. I even tried raising the legs of the dipole and rerouting so as the wires don't touch tree limbs (only a couple at least and the wire is insulated, solid copper #12). It is fed by one solid piece of BuryFlex coax up to the tower switch and the same coax from the switch box into the tower. My TH-11 beam functions perfect so I know it's not the switch box.

My question: Is this dipole too short now for 160 meter? Should I just cut it down to a 80 meter wire? Any constructive advice will be appreciated.

73s,
Paul - K5HSV

Hi Paul,
If you have made no changes in the antenna, it will continue to work
just fine on 160. The indicated SWR "in the shack" has changed
because of the change in co-ax length, the actual SWR at the antenna
is the same since you have made no changes. Measure the SWR at the
switch and since the feed line length will be different so will the
indicated SWR. You can also patch in a length of co-ax in the shack
and see a change. Take a look at http://w2du.com/Chapter01.pdf for the
reasons for what you are seeing.
If you radio doesn't like the SWR use your tuner...the stations at
the other end will never know the difference.

Thanks Bob,
I was wondring about installing a DXEngineering DXE-BAL050-H10-AT to
the dipole. I have read some great stats on that balun, which is
specifically made for wire antennas, used for multiband operation.
from what I've read on eHam.net it works very well.

Opinion on this idea? I do have a tuner in the shack that works
well. Thanks for you information and the link which I found very
helpful as well.

73s,
Paul - K5HSV

Hi Paul,
Glad to help.
I wouldn't bother with a balun at all for a low single band dipole.
The DXE-BAL050-H10-AT is a nice well built balun . My own preference
is for a choke balun of the type made by slipping ferrite cores over a
length of co-ax for use with a dipole.
Perhaps we will run across one another on top band.

Can you get a lower swr on a frequency within the 160 meter band?
You may just want to lengthen or shorten the ends to get a decent swr
on the frequency you want to operate on.

From: Steve Eisenberg
Topic: 2839 Message: 2839

Hi, All:

This guy sells under "pennradio" and possibly a few other names, and one might want be extremely careful before choosing to deal with him. I won't bore the group with the sordid details, but Gazak, who spells his name "Gazek" for eBay purposes, should be avoided at all costs, in my opinion. Details upon request, and/or you can Google him.

Hi,

I use the MFJ-974HB and I love it. I have two antennas. One is a 137' end feed Zepp and the other is a 144' loop. Both are feed with 450 ohm balanced lines. The MFJ-974HB tunes anything I want. I put in a good station ground and if I just use the side of the line that is attached to the 137' wire I can even load it up on 160 meter.

If you go to the MFJ web site you can down load a manual for the 974B. That was the model without 160 meters I think. I have not been there for at least a year and maybe they have the 974HB manual there now.

Keith,

The main thing with tuning with the 974
is to make sure you stop transmitting to
change the inductor setting. I have
heard from others that they overheated
the inductor
and burned off contacts by changing the
inductor while transmitting.

I also recommend getting a dc cord or
make one for the lamp. I usually keep
the radio
room lights down and the lighted
SWR/Power Meter is neat. The first
month I did not
have the lamp lit and I was surprised
how much easier it is when you can see
the needles.
LOL 58 the eyes get a little dimmer.

Clint,
A while back I rigged a wall wart transformer to the light(s) inside the meter thru an RCA phono jack on the back of the radio that grounded when you keyed the radio. So that when you keyed the radio the meter light(s) lit and when you unkeyed the light(s) went out.
I liked it.

Dear Ace,

Now that is a project I like. I think I will dig out my
TS-440 book and look around. I bet that maybe I have a
keyed 12 volt line on the acc/transverter connection.
I also toyed with the idea of a foot switch for keying during tune.
Fast and responsive.

Thanks again for another outstanding idea.

Clint,
Glad you like the idea. I just connected the 12 V negative lead to the center of the RCA phono jack on the back of the radio that
grounded when you keyed the radio. I think the jack I used was intended to key an Amp. I actually used a little less than 12V DC to extend bulb life, Also bulbs last longer on DC than they do on AC.
Let me know how it works out.

I use a foot switch and a Heil boom with Radio Shack by SHURE mic on HF. I plan to add a second mic on the boom. If anyone wants plans on how I will mount 2 mics on the Heil boom, let me know, as I know how to make it look factory original.
I plan to series the two mics for better audio fidelity. I have 2 matching Radio Shack by SHURE discontinued cat # 33-1070C mics . They are 300 ohms impedance each. My radio calls for 600 ohms input. These mics are identical to the discontinued SHURE VP64 mics. Not the newer, less quality SHURE VP64A or VP64B mics.

Dear Ace,

Now that is a project I like. I think I will dig out my
TS-440 book and look around. I bet that maybe I have a
keyed 12 volt line on the acc/transverter connection.
I also toyed with the idea of a foot switch for keying during tune.
Fast and responsive.

Thanks again for another outstanding idea.

From: w4dsb
Topic: 2851 Message: 2851

First thanks for this wonderful group, lots of info here!
Looking to put up my first loop
looking at making it for 40m but also multi band with a tuner I read
so many articles about the skywire loop that i'm starting to be confused

do i need to feed with coax or twin lead?

balun or no balun?

ratio of the balun ?

I plan on running no more than 100 watts into the loop

thanks, W4DSB

2852. Re: [SkyWires] Newbie here with questions

Open wire is usually the better choice for multiband antennas. This is because the high swr doesn't matter nearly so much because open wire (ladder line, twin lead too) has so much less loss than coax. When using coax you need to be aware of how much additional loss will take place as swr rises. When using ladder line/twin lead/etc, it really isn't all that important.

(You can see these comparisons in the ARRL Handbook and ARRL Antenna Books, if you have them. Look for something called "Additional Loss Due To SWR" -- If you get World Radio Magazine, there was an article on this topic in the most recent issue.)

The biggest concern with open wire, ladder line, etc, is keeping it several inches (more is better) from metal, wet wood, etc. This makes it difficult to go through the wall ;)

You can still use the open line in these conditions, but you have to understand that it becomes unbalanced (too close to something -- all kinds of things), and once it is unbalanced, it becomes an active part of the antenna, radiating RF.

So some people will use coax to get outside and then switch to open wire (or ladder line/twin lead/etc). That may be the point where a 1:1 current balun may help. If you know the impedance will always be "too high" you may wish to use a 4:1 balun. Ultimately if you have a transmatch with a wide enough tuning range (meaning the ability to transform impedance from one value to another) that balun ratio doesn't really matter all that much in the greater scheme of things.

You can always refine it later (and that is part of the fun!) so don't worry overly much about the details. Just get something up and keep accurate notes as to our swr, impedance, and whatever you can measure. Then keep reading. When you think something may be an improvement, try it! Measure it, use it, and compare that to your records. Antennas are arguably the most approachable aspect of ham radio, so enjoy playing with them!

Good luck!

Thats where a big part of my confusion came from. the ARRL handbook
said to feed it with 50 ohm coax with no balun.

The ARRL antenna book states only use ladder line
>
SO I think i will give it a whirl with 400 ohm ladder line to the
tuner and see for myself!

Ah, yes, I can see how that'd be confusing. Perhaps I wasn't clear enough when I mentioned these books. I was referring to the additional losses due to swr, and only that.

Let's see, thumbing through the handbook...

2008 Handbook, Fig. 21-4 and Fig. 21.5; Pgs. 21-6 and 21-9. Beginning with the section entitled "Losses in Transmission Lines" (pg. 21-6) reading through "The Transmission Line as Impedance Transformer" (pg. 21-9).

But you're right, the bottom line is try it for yourself. Any balanced transmission line from 300 to 600 ohms should be fine (open/ladder/window/twinlead/etc). And certainly better than coax for your multiband use. I don't think you'll benefit by using coax, so if you must, keep those runs as short as possible because they'll get very lossy when under high swr.

Just be careful going through the wall to get outside, so you don't unbalance any balanced line (it'll then radiate RF as an antenna element). One way is to double up a short length of coax running from your transmatch through the wall and then connecting that directly to the balanced line. You ground only one end of the pair-coax and use the center conductors as you would balanced line. The Antenna Book has a line drawing of this: 2008 edition, pg. 24-21, called "Shielded balanced transmission lines using standard small-sized coaxial cable...."

The facing page of the 2008 Antenna Book (Fig. 23) has the coax attenuation chart, but I didn't see the chart for the additional losses due to swr. That must be elsewhere. I can't imagine they wouldn't have it in the Antenna Book.

Hi,

Starting with a full size loop for 40M (1 wavelength in circumference) the feed point is balanced with an impedance in the range of 100 ohms. The easiest and most reliable way to connect the loop to your rig is to connect 50 ohm coax directly to the feed point, which will limit you to single band operation (40M). This method is a bit of compromise in that the match is 100 to 50 ohms and balanced antenna to unbalanced feed line. The power loss due to standing waves will be acceptable; the SWR your rig actually sees will be in the range of 1:1 to 2:1 depending on the length of the feedline ... you could have a simple antenna tuner at the rig to make sure your rig is completely happy ... but generally not necessary.

Some operators use a balun (at the feed point) between the antenna and 50 ohm coax, which is controversial. This balun would be a 1:1 balun since the impedance of the loop and the coax is close .... its purpose would be to provide a transition between BALanced antenna and UNbalanced feed line (thus BALUN). Supposedly this would prevent antenna currents on the outside of the coax feed line. By the way, the efficiency of a balun is best at these relatively low impedances .... baluns always become less efficient at higher impedances.

All of the above pertains to a single band antenna ... in this case 40M. If you want to operate your loop on multiple frequencies e.g. 40-10M ... multi-band operation is always higher than the natural resonant frequency of the loop .... then forget the forgoing directions. The high SWR and losses preclude using direct feed with coax. An efficient multi-band feed system always requires the use of low loss balanced feed line such as 450 ohm ladder line or 300 ohm TV twin-lead. Connect the

balanced feed line to the loop feed point (balanced to balanced) ... no transition problem here. However there will be a great impedance transition .... thus the reason for using line with low loss .... this makes the loss acceptable.

Balanced feed-line is not as easy to deal with physically as coax ... ideally the balanced feed-line can be brought right to the operating position and connected to your antenna tuner. Some people will say that this creates a problem of feed-line radiation .... NOT TRUE. Balanced feed line connected to a balanced antenna carries RF that is out of phase and self cancelling at all points along its length. The result is there is little radiation beyond a very short distance around the feed-line.

The balanced feed-line is then connected to the balanced input connectors on your antenna tuner. Almost all modern antenna tuners are unbalanced tuners ... and they come with a built in balun, usually 4:1 to provide the transition of BAlanced to UNbalanced. Now here is a point where a number of Hams use their own 4:1 baluns. Running a balanced line is generally a reasonable proposition from the antenna to the outside of the house near the operating position. However, it is difficult getting it in to the house to the operating position. What is often done is to bring the balanced feed-line to the outside of the house as close to the operating position as possible and to terminate it at the balanced input of a 4:1 balun. A coax line is then run from the un-balanced output of the balun to the unbalanced input of the antenna tuner. The idea is that the efficient low loss balanced line is made as long as possible to a balun and then the remainder of the distance is made up with coax to the tuner. Often the loss in the short length of coax is acceptable.

This should answer your 3 questions.

True -- provided the feed line remains balanced. Should it become
unbalanced this is no longer true.

How to *un*balance balanced line?

A good way would be to duck tape it to your aluminum siding. Lay it on
the earth. Or stick it through the window and smash the window sash
closed onto it, especially if it is a metal window frame or if it is
wrapped in a wet towel. (Yes, I've done most of those naughty things at
one time or another!)

A very tricky way I discovered to unbalance my balanced line was letting
it get too close to my lead crystal ashtray. Who knew they really used
lead in those these days, and that there was enough metal in it to
unbalance the 450-ohm ladder line?! That one really threw me for awhile!

> What is often done is to bring the

> loss in the short length of coax is acceptable.

Yep. This is often the easiest solution. Coax is good for routing along,
through, and under just about anything! It just isn't very good while
experiencing high swr, which is why such runs are minimized.

You'll have to consider your application. Are you only running outside
the wall, 10 or 20 feet of coax? That's usually fine. Are you not only
getting outside but also running down the length of your basement
ceiling across heating ducts and water pipes for another 100 feet to the
far corner of your house? That's a lot of loss when high swr is on that
line. That example maybe is not so fine.

So we can't really say with perfect confidence what should be your best
bet. But these are the guidelines and kinds of things we think about
while trying to determine this issue.

Keep us posted on your progress, and let us know how it works for you.
It is always nice hearing how these projects turn out.

Hi Erik,

Yes, proper dressing of open line feeders is a kind of art in itself. The basic rules are never bend or change direction more than 90 degree at one time ... don't go parallel to metal objects ... keep the feeder at 90 degrees in relation to the antenna as far as possible, keep feeder supports as symmetrical as possible to the feed line, etc. etc. I am sure there are any number of good tips.

The best solution ... and by definition it is a long term solution is if at all possible to bring the feed line right up to the antenna tuner at the rig. Then, in the best of all possible worlds, avoid a ferrite balun altogether and use a balanced antenna tuner. Many/most of the problems that occur in matching to all bands/frequencies are the result of the performance of the ferrite balun. If you have a balanced antenna fed by well dressed balanced feed-line connected to a balanced antenna tuner you will find it a rare thing to find a frequency that won't match to the xcvr.

The efficiency of this kind of antenna feed system is a joy .... works wonders with QRP ... and no problem handling a full gallon !!

Heheh, now of course you invite the disclaimer that open wire balanced line is somewhat better during inclement weather than window line, which it somewhat better than ladder line, which is somewhat better than twin lead. Less area of the supporting material means less dielectric losses and less area for water to collect upon during a rain storm and less opportunity to start ice building up. Bla, bla, blah.

Please note, these are all very small pros/cons vs. the original question of balanced line vs coax ;)

Erik n0ew
PS: As with balanced line, the above velocity factor of my humor is about 95% :)

> difficult to go through the wall ;)

In my case, I have two loops, both fed with 450 Ohm ladder line.

Both of the ladder line runs are passed through the wooden wall of my home, as my way of getting it into the house.

My MAIN LOOP's ladder line is run through the 'built-rite' (buffalo-board) and the siding of my garage; This is then routed to my Icom AH-4 auto-tuner, kept well clear of metal, wiring. (12' of coax is routed from the tuner into the family room, to the radio.)

My 'new loop' is fed into the house at the other end of the house; I drilled a one-inch hole through the siding, buffalo-board and insulation to allow the ladder line to be passed directly into the basement shop.

My 'main loop' runs EXTREMELY well. My 'new loop' is so-so, but this is because the shape is poor! (It is a well-flattened triangle, with too-sharp ends, or corners. Per input, my 'poor loop' is suffering from CURRENT CANCELLATION' at the sharp corners.)

My question: Is it all that bad to pass ladder line through the house sidewall? I can expect and assume that the offense would be noticeable (or worse) if the siding is wet!

Or, am I simply LUCKY that my 'main loop' is happy on all bands, even though I have allowed the ladder line to pass through the wall of my garage?

-Eric's comments continue as follows:

> So some people will use coax to get outside and then switch to open
wire
> (or ladder line/twin lead/etc). That may be the point where a 1:1
> current balun may help.

In my case, the ladder line in the basement shop is only 4 feet long. (This is the part of the ladder line that is actually INSIDE the house.)

I started out with a 4;1 balun, and found that the RX and TX signals were better if I simply attached the coax's PL-259 to the ladder line.

I got a large 1:1 (160-6 Meter coverage, 1.5 Kw) current balun; This allows the same performance as if I simply attached the ladder line to the coax's PL-259.

So, I am committing two sins:
1. I passed the ladder line through the basement's wooden wall.
2. I had a 1:1 balun, but am now NOT using this.

I am presenting this as I would like more info (data?) on the passing of ladder line through a wooden house's wall, and I am also looking for opinions on my use-or-not-use of either balun.

Thank you!! (Great group!!)

-Mike-
K0JTA
-One more thing: Where can I find INFO or OPINIONS on this CURRENT CANCELLATION thing?

The only "offense" will be if the line becomes unbalanced and begins
to behave as a radiating element as opposed to transmission line. Beg
borrow or steal a current tester and measure it. That'll settle the

issue.

Yes, it'll be more likely to be worse when raining.

RatShack recently had a cheapie on sale, and Fluke makes pretty good ones that fit on some of their VOM's. If you have older hams around borrow a grid dip -- rather have then come out with it, so they can show you how it works. MFJ antenna analyzers can also be rigged with a coil to measure such things.

heeheh, 'sin' is too strong. First test for unbalanced line. #1 may or may not be a problem. That state hasn't been identified yet. Point #2, does your transmatch have a balun in it? Some do, and some don't. But this too is largely about keeping the transmission line balanced. Maybe that isn't a problem in your case. The other part is a ratio balun (4:1, 2:1, whatever) to alter the antenna's impedance to something closer to the lines. Again, maybe an issue in case and maybe not.

So don't assume there is anything wrong with your existing systems. They may be just fine.

Don,

Yes, open wire line is a lost art. I think I am the only ham in my club of
25 that uses it. Do not confuse ladder line with open wire line. Some
folks do.
Open wire line is not adversely affected by rain, while ladder line is.

I can run full power and get no rf in the shack (1kw) and the open wire line
enters
the window through a 12" x 8" plexiglass panel next to the air conditioner.
The Heath SA-2060,
is located 1 foot from the panel, and can tune 160-6M.

Now if I can just finish the 1500' sky loop through the jungle! Now it is a
lonely 800' dipole. ;-)

73's

Glen K4KV

I just wanted to commend the folks who have been giving such good
advice re: ladder line. One more advantage over coax--you don't have
to worry about water getting into the feedline!

From: Don Keith
Topic: 2851 Message: 2867

Beautiful, Glen! I hope I get to hear that 1500-foot beauty on the air soon!

I continue to be amazed at how many hams are afraid of any kind of balanced feedline. I used to be. Coax ruled! Now that I've used window line for three different antennas, coax will be the exception rather than the rule from now on.

I still use 450-ohm (give or take a few ohms) "window" line, primarily because it is cheap and readily available. But my wife has noticed that her plastic clothes hangers have been disappearing from the closet. Someday I'm going to chop those babies up into six-inch pieces and make myself some true open-wire feedline for my big loop.

Oh, so many potential antennas and so little time, space and wire!

From: G B
Topic: 2851 Message: 2868

Don,

Yes, I wish more people understood balanced line, and how it eliminates all kinds
of antenna problems. I cannot tell you how many antenna failures I and other guys
around here have were because of coax issues.

My long dipole, as I call it now in the unfinished stage, beats the pants off my 40 meter
delta loop at 25M high. However, the 2 element quad at 27M high beats the pants off
the long dipole on 20M.

I read a piece by a guy who's tower was 1200 feet from his shack. His solution: ran #4
copper open wire line from poles 6' to remote tower. measured 0.3 db loss on HF ;-)

Of course, the #4 is way over kill. I use #14 with black poly pipe (underground sprinkler stuff).
I bought it from a guy for $0.50/ft, but you an make it for half of that. #14 is $0.095/ft and the
two 4" pieces of polypipe is pennies.

160M is my only problem child. My inv-L is the only antenna with any dx capability. I have a full sized
delta loop, but apex is only 75' high. Going to put up 120' tower in the spring, and move it to that.
Perhaps that will help. I know my 75M delta loop at 25M high does dx very well.

Take care and nice chatting,

Glen K4KV

Beautiful, Glen! I hope I get to hear that 1500-foot beauty on the air soon!

I continue to be amazed at how many hams are afraid of any kind of balanced feedline. I used to be. Coax ruled! Now that I've used window line for three different antennas, coax will be the exception rather than the rule from now on.

I still use 450-ohm (give or take a few ohms) "window" line, primarily because it is cheap and readily available. But my wife has noticed that her plastic clothes hangers have been disappearing from the closet. Someday I'm going to chop those babies up into six-inch pieces and make myself some true open-wire feedline for my big loop.

Oh, so many potential antennas and so little time, space and wire!

2870. Wow, a Loop Skywire group!

Yahoo group: SkyWires
Date: 2008-02-02 02:02:58 UTC
From: Dave
Topic: 2870 Message: 2870

I was surprised to find such a group...thought the antenna was so simple that hams would just "put one up".

It was at an Atlanta Radio Club meeting in 1983 when I heard W0MHS present his "Loop Skywire" talk. In fact, I think he had not named the antenna that yet - but someone in the club dubbed it thus, as "Return of the Jedi" had just been released and Luke Skywalker was on everybody's minds.

At the time, I was renting a half of a duplex, which had a fairly small back yard, but over 50 scrub pines in that back yard. I got a 500 foot spool of #14 THHN and got the wire in the trees as high as I could using a 12 inch crescent wrench tied to a string. I didn't stop until ALL the wire was in those trees...I think I went around the back yard twice with the wire, then snaked it along the hedge at the back yard into the adjacent (renter) neighbor's yard then back. Too cheap to deal with a feedline, and not wanting to muck about with anything too "damaging" to the rental house, I did not feed it with any normal type of feedline. Instead, I found some #20 gauge hookup wire, white and black, and made my own twisted-pair transmission line. That was unobtrusive enough to run from one of the trees onto the roof of the rental house. From there over to above the back door, over the gutter, down a bit of the back wall, then it fit between door and weather gasket (no screen door) into the house. Since I was a recent college grad with no furniture, I had no kitchen table, but instead, had some cardboard boxes holding my Drake B-line. I used an MFJ "econo tuner" - an unbalanced tuner - didn't worry about baluns or any of that.

I never worked any serious DX with it, but then it wasn't even 20 feet up. It served better than I expected, considering that it was a truly invisible antenna, being buried up in those trees. But I seemed to have no difficulties working most of whoever I could hear. That was at a time in my ham career when I had not yet discovered microphones....straight key only.

A few years later when I moved, I tried to take it down - no luck. The pine trees had grown around the wire. So the antenna stayed, although I did clip the "feedline".

Years of being mainly off the air due to housing and career complications, then when I got re-activated finally I was in California, this time I wanted to be mostly a DXer. So it was wire verticals and high dipoles on my micro-lot (50 X 70 feet)...and I did a decent job working CW DX with those antennas.

Another career move took me to Oregon, where I am surrounded by, and becoming engaged with ARES and other public service work...and NVIS antennas are again potentially useful. So, while I have my nice elevated vertical with tuned radials that is a champion at DX, and I also have my nice 70 foot high 80 meter dipole for coast-to-coast 80 meter QSOs, I am once again contemplating a loop. My neighbor has one at 8 feet high, and he swears it's the best antenna he has for checking into the local, state, and regional NTS nets on 80 and 160.

From: Bruce Conner
Topic: 2870 Message: 2871

Hi Dave,

Well, due to weather breaking my 30 foot wooden towers, I have my horizontal 80 meter delta loop up at about 12-15 feet at the moment. Last night I actually heard Germany and Spain on 80 meters with a reasonable signal (I'm East Coast US). I was busy with something else, so I didn't try to work them. I used that antenna at the full 30 feet to work Europe on 20 meters with 1 watt, so don't think of it as just a NVIS antenna, although it will work well for that too, especially near the fundamental length. I run mine with home made ladder line (3 inch) and an old Harvey Wells balanced tuner. Wire is 14 ga insulated from Home Despot. Works great!

Good luck getting your new antenna up. You might as well go whole hog and use ladder line too. Makes it a nice multiband antenna that way and no need for baluns.

You may want to investigate the "S-Match" from PA0FRI which uses a minimum of components and is very suited to loops. Just finished building one.

Hi,

At first I thought you were actually referring to "Z-Match" and misspelled hi hi. I did a search on "S-Match PA0FRI" and was very impressed with the "S-Match" design. I may build a version myself as I am very fond of mult-band balanced antennas and balanced antenna tuners. Thanks for bringing it to our attention.

I used two 618T inductors (0.5 - 6 uH, www.mgs4u.com) and a 600 pF variable capacitor. Toroid is T184-2 11 windings primary and 2 x 5 windings secondary (nicely "nesting" between the primary winding). Make sure to use thermaleze / teflon coated wire for the secondary of the toroid as the voltages can be very high. Could not get teflon and used shrink tubing over the thermaleze (thermaleze is good for 2 kV and some shrinktubing will do several kV but more important it will prevent damage to the thermaleze). "Driving" the two above rotary indictors is far from light though, hi hi!

The use of two inductors allows me to "earth" the "centre" of the rotary coil and force symmetry. Alternatively I can earth one of the balanced terminals and get an unbalanced output.

Enjoy!

Topic: 741 Message: 2875

PS

My ATU started off as an "ordinary" L-C tuner as promoted by AG6K and then just rewound the input balun to an input transformer to trial the S-match design. The balun did not come back.

The transformer is a part of a tuned circuit and it needs to be firmly mounted. The windings may be locked in place with Q-dope, I used clear nail polish.

Topic: 741 Message: 2877

Shorting the green and black terminal on the right side (in the
picture) will earth the centre between the two coils which "forces"
symmetry for balanced operation.

Shorting the black terminal on the left with either of the red ones
will force unbalanced operation.

Neither shorting is required (however I like the antenna to have some
connection to earth somewhere for static and lightning protection).

Since the transformer is very close to a 1:1 transformer, you could
move the variable capacitor to the primary of the thing - put the cap
in series with the primary winding and now the cap has one grounded
leg, reducing the chance of exposing an operator to RF voltages.

Be careful how you "force" a balance on things. By grounding the
center tap of a transformer output, you have forced equal voltages and
opposite phase into the output terminals. If, when those
equal-but-opposite voltages get to the antenna, the
single-point-against-earth impedance of the two antenna terminals is
not identical, it will give rise to a difference in current on the two
legs of the transmission line, turning the t-line into a radiator.
That's why current-mode baluns (usually in the form of common mode
chokes) are preferred - they force equal currents.

You can force either equal currents or equal voltages, but not both.
Equal currents is the correct item to force, if your goal is to
eliminate feedline radiation.

Thanks for the info on the S-match, it looke very interesting, but how do you think it would work on a very large loop? My loop is two W/L on 160 , and I know it has some wild impepience's on some bands.
I use it mostley on the lower bands but some on 20m.
I havent built very much , and no experience with building baluns or toroid cores. Would the big loop change the values very much.
I do have a roller inductor and some old caps around . I have also built some coiles in the past for tuners with inductive coupling.
Dont have your e-mail but mine is in QRZ.
Thanks again Leonard,

Hi,

You can check out several articles listed on this site ....
www.dxzone.com/catalog/Antennas/Bazooka/ including a design
calculator. Just out of curiosity I was wondering how you were planing to
setup and use the antenna .. it is not exactly a light portable
antenna. But then again an 11m dipole is not all that big hi hi.

Keith (and the group)

Have been laid up in hospital and have replied to your email message in private.

I think it will work fine, it will handle some very weird difference in impedances with ease.

Nice thing is that it will "find" its own balance) or you can "force" things. Both have their advantages and disadvantages.

I am finding that at the low frequency range I get difficulty with very low impedances and at the high end with very high impedances. With a loop that should not be a problem: my 40m full wave is halve wave loop at 80 and very high impedance. On 40 , 20 and 15 the impedances are more in a "normal" range.

I am not an expert in these things (wink) but I think that if somehow
you take a bit of a distant view of the thing then you can reduced
this to a link coupled LC resonant circuit: first the link
was "removed" by using a second coil assembly (toroid) and then the
link was removed from the "centre" to the "ends" (perhaps one
could "revert" the view: instead of the tapped part being the
resonant circuit now the link is the resonant circuit). This is where
lots of confusion starts: many people try to see this as a 1:1
coupling which it ain't. It is part of a resonant circuit that has
been unusual configured. Hence the working is totally different than
with an ordinary L-C balanced tuner that is driven by a balun.

Further you are 100% correct: make sure everything is RF isolated
otherwise you could get up hurt badly. This is why I like to "earth"
whenever I can.

But when this thing is left floating it is wonderfull how much static
and other noise disappears at my location.

Topic: 2886 Message: 2886

Don't know how many of you have heard of the above twin wire designed for RF.

It was highly recommended to me as being as simple to use as coax inside the house with little interference. On can lay it directly on the floor, ceiling etc without the requirement of being suspended. Losses are appernetly extreemly low too. This is due to not using air as the dielectric like in the normal twin wire.

Have a look at this website and search for twincom cable:
http://www.titanex.de/frames/products.html

My wife is due to go over to Europe in the near future (family health) and I am going to get her to bring some of this back to New Zealand. We'll see how this will turn out.

Hello, I'm KE4NU/7 (Alan) in Western Montana. I've been using a 80 meter horizontal loop for a couple of years. Its in a kind of a rectangle configuration. The corners vary in height from about 30 to 55 ft. I feed it with 450 ohm twinlead to a 4:1 balun then about 10 ft rg8x into the shack to a tuner. It has been a great performing antenna. I've used it on 160-6 meters, worked a bunch of dx. On 75 I've worked South America, New Zealand, Australia, and a lot more during contests. This is not just a antenna for close in contacts.
I've also tried bringing the twin feeline inside the shack and using an old johnson matchbox. I could tell no difference on either transmit or receive so I went back to the balun.
I might ad that over the years I've tried many different antennas and plan on trying more and the loop is one the best IMHO 73, Alan

Hi Alan,

Some kind guy sent me some software plots of the RF pattern similar to yours but with a height of around 80 feet (difficult for most of us, I know). Both his experience in contests as well as the software plots demonstrated excellent DX capability.

I only I had 4 x 100 foot trees spread apart!

:)

The trouble with trees is that they're often not placed for optimal antenna work. I've got many dozens of trees on my property. A dozen 70 foot oaks are all clustered so densely together (the way Mother Nature puts them naturally) that the only way to use them as a support is to slingshot a line clear over them. There's one Douglas Fir tree well over 100 feet high, but the foliage at the top is little more then webbing. Far too weak to climb, and in such a thicket that one could not get a bucket truck nearby, and a line from a slingshot barely makes purchase.

Then, 300 feet to the north, an abandoned Christmas tree farm, 50 or so Doug Firs of about 30 feet in height, which I can approach only from one side on account of the terrain and several farmers' animals.

So, as it turns out, I'll be needing to plant towers, and in that case, the presence of the trees inhibits guy lines...thus forcing me into more expensive cantilevered towers.

For now, I'm using a vertical, supported on a man-made tree house, and an 80 meter inverted vee, its apex vaguely situated somewhere in those oaks. My neighbor insists that I should do a loop, around the perimeter of the property (1800 feet). If I did that, one corner would be at 30 feet, and the remaining three would be at six feet, as the support structures in most of the perimeter consist of six foot fences.

Why can't trees be where you need them?

;)

I guess I'm lucky with the placement of trees on my property. First got my ticket in 1959. In 1964, my new wife and I picked out a building spot on the old home place, hoping one day to build there. That year, I set out a bunch of Southern pine trees around the place with placement of antennas in mind. We did not build there until 1980. Now, after 44 years these trees are huge, but thanks to Hurricane Katrina, I lost four of them. I use a potato gun, or "spud gun," as some people call them to place my lines over the top of the trees.

73,

Phil - K5FSP

Has anyone ever used one of those cheap crossbox pistols to shoot lines over limbs. You can get fishing line reels for them. You usually find them either 50lb or 80lb on ebay. Price seems right most of the time. Before we bought this place, the last place had 1 tree on 7 acres and wasn't very tall...73, Alan

==========

Yes... I have used them to put wire antennas in trees about 75 feet
above the ground.

They sell on eBay and also on eHam.net.

They're a slingshot with a fishing reel.

HIGHLY recommended (pun intended).

It looks like that at present Radioworks only offers the Superloop 80. Wonder if anyone has worked with the 40 version and what their experiences are.

I noted that ladderline is being used for the stub - if I do decide to create one then I will have to come up with an alternative since I cannot get my hands on ladderline easily here down under. May just make one continued loop and then just make the wire closely spaced. Has any tried this?

Thanks

a tree trimmer here in Houston put a line over a branch about 50' up for me and how he did it has changed my mind since the "wrist rocket" is a POC of the first order. (line is too light, should be 75# braided). What he did was to unwind his yellow cord off his 1x4 with V cuts in each end ... about 150 feet of it (remember, tree trimmers have to get ropes up there to cut limbs,etc) and laid it out carerully on the grass in front of him. he then took the end which terminated in a small leather pouch filled with about a pound of ball bearings... might have been half that but it weighed plenty and then dropped it towards the ground about 30" worth. while fixing his stare on where he wanted the pouch to go, he began whirling this pouch underhanded, at his side and when he was ready, he let go of it.

He put it exactly where I wanted it in the top of my neighbor's street front 60 yr old elm tree. the pouch was heavy enough to drop straight down thru the foliage and small branches to the ground. I then piggy backed some 700# test black line after he pulled the pouch back up to the fork, then dropped the pouch and I pulled the pouch down so that i could get my suspension line down.

anyway, he untied his cord from the board (it was that yellow cord that most builders use over and over again to mark between corner stakes where the foundation form boards will go), and pulled the rest of it thru the crotch and then rewound it.

this works better than anything short of climbing or using a ladder to get a line up in a tree AND BACK DOWN on the other side. takes practice to get it to go where you want it but heck, it should be fun pitting your hand-eye coordination against such a task.

From: Alan Wilson
Topic: 2901 Message: 2901

This is how I did it for the last few years, I used a compound bow and practice arrow. I wrapped some solder around the tip (to ad weight). I tied 30 lb test fishing line (spider wire) to tail end of the arrow. I had the fishing line on zebco33 on the bottom half of fishing rod. I had someone hold the rod and reel or placed in a bucket. With the cast button pushed and a little line free from the reel and not tangled in grass, rock, etc, I fired the arrow and if the arrow went where I intended it to go. The added weight on the tip of the arrow made it head back down to the ground easily most of the time. After retrieving the arrow I removed the fishing line and tied it to the 1/4" line. I also taped it to make it smooth and less likely to hang up. I pulled line back over with the fishing reel. I tied the insulator or whatever to the end and tied the two ends of the 1/4" line together so that is was a continuous loop. That way I could pull it up or down when needed. I just thought using this method with a crossbow pistol with the attached fishing reel would be easier. Cheap as they are I think I'll try it anyway, hey if nothing else I'll have something to hunt gophers with...73, Alan

I use a spud gun to get my lines over tree limbs. I may have posted this before. I can't remember. Just make sure you don't have any irate neighbors, or local laws against its use before using the spud gun. For just a few dollars, you can construct one. If you wish to construct one, you can use my plans, or Google "spud gun." There's thousands of articles on spud gun construction. The first time I used mine, I had 600' of nylon masonery line coiled up in a bucket. I did not tie the other end of the line to anything. I fired the gun, and it took away all the line, and over the trees it went!

The following is my experience using a spud gun, or potato gun:

Spud Gun

Construction:

Cut 2 inch Schedule 40 PVC to a length of 36 inches for the barrel.
Cut 4 inch Schedule 40 PVC to a length of 18 inches for the firing chamber.
Install 2 inch female x 4 inch female Schedule 40 PVC x-over on one end of the 4 inch x 18 inch firing chamber. Install the 2 inch x 36 inch barrel. Bevel the outside of the end of the barrel to aid in cutting the potato to size.
Install 4 inch threaded female x 4 inch slip-on Schedule 40 PVC on the other end of the 4 inch x 18 inch firing chamber. A 4 inch bull plug will be used in the threaded end later.
The Coleman lantern striker was purchased in the camping section of Wal-mart for about $3.00. It is installed as follows: Disassemble the striker and discard the mounting tab. Remove the knurled knob and slide the striker out of the bushing. Drill a hole in the 4 inch firing chamber as near as possible to the 4 inch threaded end. This is so the flint in the striker can be changed easily. Thread the bushing from the inside of the 4 inch allowing the bushing to make its own threads. Reassemble the striker.
Allow glue to cure for about 18 ? 24 hours before test firing.

Installing line over tree:

Cut about a 6 inch piece of 2 inch PVC to use as a jig for pre-cutting the potato. Bevel the outside of the end as was done on the barrel.
Cut potato to size and remove from jig.
Cut a square piece of cheese cloth ? Purchased from the sewing/cloth section of Wal-mart.
Place the potato on the cheese cloth and tie the four corners together with the nylon masonry line. Spool off the estimated amount of line to go over the tree and back down.
Coil the masonry string in a bucket.
Place the wrapped potato on the barrel and push down about 30 inches with a wooden dowel rod.
Remove the 4 inch bull plug from the end of the firing chamber holding the plug just above the threads. Make sure the threads have a light lubricant on them.
Spray about 3 seconds worth of Brute aerosol deodorant, hair spray, or whatever. Check for a butane or propane ingredient on the can.
Hold the gun to your side with one hand on the barrel and at a 45 degree angle to the top to the tree, and fire away!!! The recoil is very light.

With the cast button pushed and a little line free from the reel and not tangled in grass, rock, etc, I fired the arrow and if the arrow went where I intended it to go. The added weight on the tip of the arrow made it head back down to the ground easily most of the time. After retrieving the arrow I removed the fishing line and tied it to the 1/4" line. I also taped it to make it smooth and less likely to hang up. I pulled line back over with the fishing reel. I tied the insulator or whatever to the end and tied the two ends of the 1/4" line together so that is was a continuous loop. That way I could pull it up or down when needed. I just thought using this method with a crossbow pistol with the attached fishing reel would be easier. Cheap as they are I think I'll try it anyway, hey if nothing else I'll have something to hunt gophers with...73, Alan

Just a thought here, why not put this in a text or PDF file and put a copy of it in the files section of the group, also if you have pictures that would be nice too. As far as that goes why not anyone else that has a favorite way of getting their antenna 'up there' in the air do likewise, put it in a file or picture(s) and put it in the files area. That way if someone is looking for an idea they might be able to get some ideas from you that might work for them.

Just a thought.

Subject: Re: [SkyWires] Lines over tree limbs

I use a spud gun to get my lines over tree limbs. I may have posted this before. I can't remember. Just make sure you don't have any irate neighbors, or local laws against its use before using the spud gun. For just a few dollars, you can construct one. If you wish to construct one, you can use my plans, or Google "spud gun." There's thousands of articles on spud gun construction. The first time I used mine, I had 600' of nylon masonery line coiled up in a bucket. I did not tie the other end of the line to anything. I fired the gun, and it took away all the line, and over the trees it went!

The following is my experience using a spud gun, or potato gun:

Spud Gun

Construction:

* Cut 2 inch Schedule 40 PVC to a length of 36 inches for the barrel.

* Cut 4 inch Schedule 40 PVC to a length of 18 inches for the firing chamber.
* Install 2 inch female x 4 inch female Schedule 40 PVC x-over on one end of the 4 inch x 18 inch firing chamber. Install the 2 inch x 36 inch barrel. Bevel the outside of the end of the barrel to aid in cutting the potato to size.
Install 4 inch threaded female x 4 inch slip-on Schedule 40 PVC on the other end of the 4 inch x 18 inch firing chamber. A 4 inch bull plug will be used in the threaded end later.
* The Coleman lantern striker was purchased in the camping section of

Wal-mart for about $3.00. It is installed as follows: Disassemble the striker and discard the mounting tab. Remove the knurled knob and slide the striker out of the bushing. Drill a hole in the 4 inch firing chamber as near as possible to the 4 inch threaded end. This is so the flint in the striker can be changed easily. Thread the bushing from the inside of the 4 inch allowing the bushing to make its own threads. Reassemble the striker.
* Allow glue to cure for about 18 - 24 hours before test firing.

Installing line over tree:

* Cut about a 6 inch piece of 2 inch PVC to use as a jig for pre-cutting the potato. Bevel the outside of the end as was done on the barrel.
* Cut potato to size and remove from jig.
* Cut a square piece of cheese cloth - Purchased from the sewing/cloth section of Wal-mart.
* Place the potato on the cheese cloth and tie the four corners together with the nylon masonry line. Spool off the estimated amount of line to go over the tree and back down. Coil the masonry string in a bucket.
* Place the wrapped potato on the barrel and push down about 30 inches with a wooden dowel rod.
* Remove the 4 inch bull plug from the end of the firing chamber holding the plug just above the threads. Make sure the threads have a light lubricant on them.
* Spray about 3 seconds worth of Brute aerosol deodorant, hair spray, or whatever. Check for a butane or propane ingredient on the can.
* Hold the gun to your side with one hand on the barrel and at a 45 degree angle to the top to the tree, and fire away!!! The recoil is very light.

I use a "hyperdog" sling shot. It is designed to throw tennis balls for dogs to chase. The literature says 250 feet - and I have gotten it easily up 125' over some trees. I slit the tennis ball, and put a large bolt tied with 50 pound test fishing line. I unwound a lot of line out so reduce the drag on the tennis ball going up. Works well - and a very cheap solution. It also works well with snowballs to ward off kids.

Phil,
I guess it is obvious but because you were so complete in the other steps, I'm guessing you re-secure the plug between thoe last two steps.

I also figure you should not dillydally. The faster you get the plug back on and the sooner your fire, the more effective the propellant - right?

Paul,

I did omit that step in error. You are correct... The faster you get the 4" plug in the more effective your propellant is. I have plans to install a 2" pvc ball valve in that end using a 4" npt male X 2" female x/o and install the 2" pvc ball valve. That way, all you have to do is open the valve, charge your combustion chamber and close the valve. I believe that would work much better.

73,

Phil - K5FSP

From: Jim Dunstan
Topic: 2901 Message: 2907

At 06:11 PM 2/17/2008 -0500, you wrote:

Hi,

I have suspended wire antennas from tree branches for years ... mine are in the 50' bracket. I have always used a good quality sling shot, a good size lead fishing weight, with a colorful silk trailer (my biggest problem was finding the weight after it lands in the brush hi hi ... really helps to have a second pair of eyes following the flight path. I use a fishing rod and spinning reel (use one with a closed face). I found that any line more than 20lb test is too heavy.

However, once I have a decent sized line up over the best branches I found that the branches (in my trees) were flexible enough to act as springs and I never had to deal with broken antenna wire or halyards. Now wear of the halyard at the point where it goes over the branch is the weak spot. It wears and when it parts you are back to square one ... eg trying to get the line back up over that branch. There are all kinds of techniques I have seen published as to dealing with this weak spot ... eg pulleys & weights etc...

The simple solution I have come up with solves the problem and once I started using it I never had to re-string a halyard again (25 years now !!!). It is so simple it sounds silly. All you do is tie the halyard so there are 2 ropes at the point they cross the branch. The main halyard is tight and carries the weight and experiences the wear .... the other parallel portion is slack enough that it does not experience wear and simply takes over when the main halyard parts. The other reason I keep the safety line loose is that when the halyard parts the antenna sags and you notice it. All you do is tighten it up and plan the repair at your convenience.

Mark the end of your halyard with black tape every 10 or 15 ft .... so that when you lower it you will know approximately where it crosses the branch .... then tie in your second rope parallel about 10' or so either side of the crossing point. When you pull it back into position you will see that the doubled portion bridges the crossing point (and is loose enough to prevent wear).

You are not powerless!

The Barn Door for this group is open to Spammers !

Looking at the Group's settings
**** Membership does not require approval ****
Messages do not require approval
All members can post messages
Email attachments are permitted
Members can hide email address
Listed in directory

**** Membership does not require approval **** is the main problem.
It let's anyone in, spammers and the like!

The solution for preventing future spammers from joining is simple.

The owner of the group needs to set the group so that Membership
requires approval, and if new perspective members don't specify their
Amateur Radio callsign or their interest in Amateur Radio Don't let
them in.

This is what I've used to keep the following Yahoogroups SpamFree
TexasHams
TexasVHF
W5SFA
BrenhamTXAmateurRadio
and a few others that I am the owner of, and most of the groups that
I am a member of us this same preventative measure.

When new members request to join my groups, it takes me or one of my
moderators about 5 seconds to decide and then either approve or deny
their request.

Hi all,

I am not overly sensitive .... unwanted Email ... whether on a discussion group or in general is a reality of modern life. I am sure the moderator/s will do what they can ... in the mean time I have no problem with the delete key ... in fact I often delete posts that are of no particular interest to me in any event .... after all, I have to keep my Email database a reasonable size hi hi.

Enough said .... all on this discussion group are encouraged to delete this message .... hi hi (fourth key from the right on the bottom ... on my keybrd)

2924. Cymco Im Antenna Tuner

Yahoo group: SkyWires
Date: 2008-02-21 15:55:43 UTC
From: naaah2001
Topic: 2924 Message: 2924

Hello Group
Just Picked up a Cymco Im antenna tuner.
Has anyone ever heard of this unit?
It has no manual, so of course I would be interested in getting my hands on that.I paid very short money for it, so that is why I took a chance with it. Thanks...

If it was only beating with a cane I think that could still be survivable.

I have worked in countries that if they would find anything with minors then you are as good as dead.

When I travelled I made 100% sure there would not be any flesh visible in any of my saved photographs. Even a bikini is off-limits in some countries!

If they do find something that only warrants "light" punishment you may discover that you are deported and never allowed to come back again. And that can seriously affect any employment contract that you may have in that country.

Did not realise that the owner of the group left it in this state and did not hand it over in a better manner. Perhaps the earlier suggestion of starting a new group may be the way to go. Suggest calling it perhaps "SkyWire 2000" in honour of living in the 21-st century? The moderators may think about starting a poll what the group feels about moving / renaming.

Is there anything the moderatos can do by contacting Yahoo administrators?

Peace to all

Nope -- don't even try!

I was on another list where this same thing happened, and
someone contacted Yahoo for help. A few days later, the list was
deleted with no warning whatsoever. The best thing to do when you
create a list is to give your moderators power enough to take care of
the list if something happens to the listowner. The next best thing
to do is to designate a new listowner if the original listowner gets
tired of it.

My opinion is that we need to create another list with a
similar name, and move everybody over there. Sooner or later
something will happen and this list will disappear and it will be
incredibly difficult to get it back together after the fact.

I just started a new Yahoo group called LoopSkywire. Just feel free (not obliged) to join this group.

Other (experienced) moderators are welcome; without restrictions!!

Here are the details on LoopSkywire:
Group home page: http://groups.yahoo.com/group/LoopSkywire
Group email address: LoopSkywire@yahoogroups.com

Ready to start?
Get the ball rolling by posting the very first group message. Then add photos, create an event, or whatever. In short, make yourself at home in your new group.

Simply drop by the LoopSkywire homepage now. To keep the online conversation moving, be sure to invite friends, family, and others who share your passion.

> I just started a new Yahoo group called LoopSkywire.

Oh good. We now have THREE Skywires groups, this one and two replacements (so far) that have been created to alleviate the spam problem.

See http://groups.yahoo.com/group/SkyWires/message/2544

No offense, but it does seem a little silly. Why not use what we've got, rather than re-re-creating it all over again and again?

Personally, I prefer Yahoogroups to Googlegroups, but that's just me. On the other hand, that could be part of the reason why the other replacement group hasn't gotten off the ground in its six months of existence.

IMO, for the replacement group to be effective, someone has to copy all the existing files, photos, links, etc. over to it. Preferably the 2900 existing messages too (so people have only one place to look), but that's not practical and as far as I know Yahoo doesn't give us any tricks that might make that job easier.

As a side note, I don't like spam one bit either, but I think the moderators here are doing a pretty good job of controlling it, given the limitations imposed by the group's owner. Spam is a major and rapidly growing problem, yet this group is mostly spam-free, in spite of it.

Because for most, it is far easier to do that and complain and whine and cry that the world doesn't protect people from themselves enough, dilute the knowledge base, alienate and offend those around them while running away, squeezing their eyes pretending the world is invisible... than make a proactive split second decision effecting only them and just hit the delete key and go about one's business as an independent soul responsible for their own lives.

If you would have taken note of what I wrote in my previous message on this subject - spam in certain countries where I travel can have some very dire consequences. It is for me - at least when I am travelling - either use a group that has no spam or do not visit a group at all.

Peace

Yes Andy, I tend to agree. We have mods here - just missing an owner. Oh well, worse things happen.

Marinus, - you say that you can be imprisoned, flogged or fined due to Yahoo Groups spam - and that you relying on a moderator somewhere not to make a mistake? Tell that to your judge :)!!!

PS - Only three groups? Along with "Ham Antennas" that makes four :)

2939. My Skywire Loop

Yahoo group: SkyWires
Date: 2008-03-02 13:09:24 UTC
From: Steve Holman
Topic: 2939 Message: 2939

Well I can report that my Loop is working well. in the lead in to the contest this weekend I have contacted Brazil, Argintine (sp), Paraguay Costa Rica and other locations. as of now it seems to favor the south which should be correct as it is fed on the north side of the loop. I am happy with the results. I need to tinker with the supports as they have taken a set and with the wind and cold the wire swoops up and down between supports so I need to improve them some.

Over all I am satisfied so far

Pretty cool, Steve. Looks like I'll have to get a hold
of a toroid and an air capacitor and some wire, then
I'll be all set to build. I guess an antenna analyzer
wouldn't hurt, either.

Topic: 2939 Message: 2941

Well I don't have an Ant. Analyzer yet. I have to sell a AT-180 for
that. My Icom 718 feeds a LDG AT-200 to 10" of coax through at Single
Point Ground Plate to a 1:1 Current Balun to Ladder line to the Loop.
The loop is Roughly 600Ft Long.

I am happy so far and with some tuning of the Supports to remove some
sag it should be in place a long time. I plan on using this as my
primary Ant. for now. I will probably build a 135" Multiband Dipole
this spring to provide a second backup ant.

So that is the plan

>>> Please check before you shoot

Check what, my air pressure?

I'm just fed up with do-gooders going off on one just because of a couple of weird messages every once in a while. So frigging what? Hit the delete button folks!

In fact, now that I'm nearly 50, I'm getting fed up with everything. I'm entering the dark ages where my youth and age are in conflict! Roll on 65 when I can relax in my old age and this stuff won't bother me :)

Callum McCormick
http://www.m0mcx.co.uk/

While others were busy thinking outside the box, I cut it up because I needed some cardboard for a project I was making.

Hello Callum,

The problem is not the spam messages once in a while. The major problem
is that this group is not fully moderated anymore. The owner left
without taking care of a good handover to the moderators.

The new group has a much better set-up and control!

Take care with your 2nd youth and enjoy our radiohobby; it will help you
through the in-between-age (I'm 54 years old and still very happy).

All,

A bigger problem than the occasional message from a spammer is the fact that even if they are not sending messages the spammer can still harvest/collect the email address of everyone that posts a message to the list, as well as any other email addresses in that message.

Anyone in the IT Field should realize it doesn't take much to write a program that reads email (a simple Telnet client task for pop servers), that then will parse through the text of every email message looking for anything and everything that has the pattern of an email address and adding it to their collection of addresses to spam or to sell to another spammer.

A lot of us on Amateur Radio are trying to be "do-Gooders", especially those involved in ARES and other Public Service Functions on both sides of the pond.

My problem is that I'm already at saturation point. I don't think I could get any more spam if I tried. Between yesterday morning and tonight, I've had 1,809 emails enter my junk-mail filter and a further 86 that were identified as SPAM but not junk email.

I kid you not, I personally get between 5,000 and 10,000 spam emails per week - and that's just my home email. My work email get's around 3,000 spam per hour. Crazy but true.

(I have some great tools to get rid of them!)

2955. Putting Up a Longwire

Yahoo group: SkyWires
Date: 2008-03-13 23:59:04 UTC
From: Jeff Stevens
Topic: 2955 Message: 2955

Hello All,

My sole HF antenna at this point is a wire dipole cut for 40m at about 35'. I'm quite pleased with all the contacts I've been able to make using the internal tuner on my TS-440 as well as the LDG-200 with my IC-718.

I'm looking to try a longwire next. I should be able to run it about 300' long about 40' up in the air. I'll run coax from my AT-200 tuner and feed it with either a RadioWorks balun or the balun that came along with my tuner.

Reading about longwires, I understand the need for a good *short* path to ground. Well, 40' up and short path to ground don't exactly go together (especially on the higher HF bands). From the feed point (on top of my house) the shortest path to ground (not going through my roof) will be a run 90 degrees off from the direction of the radiating arm, across the sloped roof and down to the ground. Will running the ground leg of the longwire 90 degrees off from the radiator be "bad"? I can run it in the same plane as the radiator with an extra few feet. Would that be better?

Once it gets to ground, I can certainly earth it well. I have plenty of ground rods available and a wet clay soil.

Considering the 50' or greater length of the ground leg, this setup almost sounds like some haphazard off center fed dipole with the short leg running in a funny direction. Mmm... I want the gain pattern of a longwire -- not a dipole...

My goal for this antenna (besides simply building another antenna) is to use it on 30m through 10m in such a way that it's directivity is oriented in a different direction than my 40m dipole. I'd also like to use it on 80m and 160m for local QSOs.

Any thoughts on the whole shortest path to ground being 50 plus feet??

Thanks!

-Jeff

Hi Callum - good morning from India. I can understand the dilemma you are in as far as your email is concerned. May be your ISP can help you a bit. We have in India

a system where all your in coming mails are kept in a separate folder, when they arrive first time from a person. You can mark the mail as spam and good mail and future mails from this person will reach your inbox only if you mark it as good mail. In this case you take pain only once to mark the mails spam or not and thereby save the routine of deleting the spam everyday. You can try if this works out with your internet service provider. The spam mail that goes to the spam folder is deleted automatically periodically. This facility is available for paid e-mail accounts only in India and not for common clients like yahoo, gmail etc.

How are things at your end? Radio wise it is very quiet here. Not much propagation happening and lot of qrm on the bands. I worked some Russians and a Dutch station and exchanged some e-qsls via eqsl.cc website.

73s and regards to you and your family. Vu3mes satyan/India.

2960. RE: [SkyWires] Re: Loops -n- more loops

Yahoo group: SkyWires
Date: 2008-03-14 14:20:22 UTC
From: Callum M0MCX
Topic: 2942 Message: 2960

Thanks all for the fun and games folks, nice to have a bit of fun sometimes, eh? Satyan, RF is alive and well here in Birmingham England - but not on the higher bands as you know! I've been playing 40m mostly.

Well folks, I've been experimenting as usual with my two sky loops (of course, these are just closed loops of wire held above the ground at three or more points) and comparing them against various verticals. Sometimes the verticals win, other times the loops do. I've had 8m verticals and longer too. Today, I've put the 12m vertical back up (http://www.m0mcx.co.uk/?p=102) fed with my trusty SG230 coupler (I may add that anyone interested in fast antenna experiments should get one of these. A tremendous piece of kit. Matches anything.)

Apart from the noise factor (loops are quiet), the vertical seems to make a better impact on transmit more often than not, unless I'm into NVIS or near NVIS (500 miles or so). Even then, up to 1,500 miles, the jury is out - either antenna can win. Beyond 1,500 miles the vertical seems to do a better job most of the time - not always, however my loops are very low to the ground, maximum height of 7 meters.

I used to have the opinion that loops were more often than not, cloud warmers. However let's face it, so are almost all low-to-the-ground HF antennas. Of interest though, VE7HA (on this reflector) sent me an MMANA file of a very high (80- foot) 300 foot sky loop that he had built with three very large trees. He claimed great things with it and fantastic contest results. I had a look at the plots. Yes, he was right.. how about 10.4 dbi gain at 5 degrees to the horizon on 10m? On 15m band, we're looking at 12.5 dbi at 7 degrees to horizon! On 20, it's as good with 10.5 dbi gain at less than 10 degrees.

Now.. This is a very different animal to the Skyloops that most people build. If you want a pile-up generator, this is the animal to have. It fundamentally, takes all your RF energy and pancakes it low to the ground in various star shapes. Very impressive - and it changed my mind on the ability of closed loops antennas.

Be prepared to get into some matching territory, or buy an automatic coupler at the fedpoint (maybe open wire feeder).

Some day I will build one, I just don't have the house for it today!

73 all, Back to my new interest, PSK31.

Hi Jeff,

First, long wire and dipole are not mutually exclusive. Long wire indicates a wire several wavelengths in relation to the frequency of operation, while dipole indicates a balanced antenna/feed system. A dipole with several wavelengths either side of the feed line is every bit as much a 'long wire' antenna as one fed against ground. In the balanced feed system the feed line can be considered to be separate from the antenna ... eg if properly installed the feed line does not radiate ... only the antenna (again note I said properly installed). Now as soon as you deviate from the balanced antenna (either loop or dipole) then it is all antenna including every inch from the far tip to the point it gets to your radio ... or the tuner. In this case ... feeding with a single wire against ground, the usual technique is to feed it at the end. If you feed the same 300' horizontal wire in the middle with balanced feed line it would behave much the same except it would eliminate the vertical radiation component as well as the difficulty of predicting grounding effectiveness. The exception is to end feed it with open wire feed line ... but then it is tricky because you need to find the appropriate length that puts a half wave high voltage point at the end at the frequency of operation.

All of this is to eliminate the conception that a dipole has some kind of fixed radiation pattern ... and it does if self resonant and a 1/2 wave in length. But a dipole does not have to be a half wave length or resonant for that matter ... it simply indicates a symmetrical aspect of the antenna in relation to the feed point ... and it is balanced. Then when you feed it the feeder can be somewhat divorced from the antenna. When you make the antenna a monopole ... eg fed against ground, the earth is the other half of the antenna which introduces radiation to the feed line and problems in making the earth behave like a decent half of the antenna.

Feeding a long wire against ground is very unpredictable in terms of performance and behavior. Generally speaking the installation you describe is 300 ft of wire in a horizontal position 40 ft high. At some point at or near one end you are going to bring the wire down the 40+ ft (little bends here and there) to your tuner and ground rod. To answer your question will a few bends in a few odd directions make any difference I would say nothing anyone would be able to detect. As far as directivity the radiation pattern of a long wire is generally at an angle off the ends.

I have used a long wire and from time to time it seemed to perform quite well ... however it also very unpredictable when you run with power eg 100 watts and up .... that is, getting the power into it without blowing things up hi hi.

Thanks all for the fun and games folks, nice to have a bit of fun sometimes, eh? Satyan, RF is alive and well here in Birmingham England - but not on the higher bands as you know! I've been playing 40m mostly.

Well folks, I've been experimenting as usual with my two sky loops (of course, these are just closed loops of wire held above the ground at three or more points) and comparing them against various verticals. Sometimes the verticals win, other times the loops do. I've had 8m verticals and longer too. Today, I've put the 12m vertical back up (http://www.m0mcx.co.uk/?p=102) fed with my trusty SG230 coupler (I may add that anyone interested in fast antenna experiments should get one of these. A tremendous piece of kit. Matches anything.)

Apart from the noise factor (loops are quiet), the vertical seems to make a better impact on transmit more often than not, unless I'm into NVIS or near NVIS (500 miles or so). Even then, up to 1,500 miles, the jury is out - either antenna can win. Beyond 1,500 miles the vertical seems to do a better job most of the time - not always, however my loops are very low to the ground, maximum height of 7 meters.

I used to have the opinion that loops were more often than not, cloud warmers. However let's face it, so are almost all low-to-the-ground HF antennas. Of interest though, VE7HA (on this reflector) sent me an MMANA file of a very high (80- foot) 300 foot sky loop that he had built with three very large trees. He claimed great things with it and fantastic contest results. I had a look at the plots. Yes, he was right.. how about 10.4 dbi gain at 5 degrees to the horizon on 10m? On 15m band, we're looking at 12.5 dbi at 7 degrees to horizon! On 20, it's as good with 10.5 dbi gain at less than 10 degrees.

Now.. This is a very different animal to the Skyloops that most people build. If you want a pile-up generator, this is the animal to have. It fundamentally, takes all your RF energy and pancakes it low to the ground in various star shapes. Very impressive - and it changed my mind on the ability of closed loops antennas.

Be prepared to get into some matching territory, or buy an automatic coupler at the fedpoint (maybe open wire feeder).

Some day I will build one, I just don't have the house for it today!

The SG230 is a tremendous piece of kit which can match anything. You still need to obey the simple rules of antennas though (eg, for verticals you will need a good ground etc) but other than that, they have a habit of becoming addictive. For the UK for instance, imagine having an antenna that will comfortably go from 3.5 to 3.8 MHz at maximum efficiency.

You will need to get your mind around "non-resonant antennas" before these come into their own because the search for 50 ohms all of a sudden becomes a thing of the past.! It really will tune (actually, they call it "couple") any antenna to your coax regardless of what the impedance and resonance your antenna is. Antennas that previously on some bands were unworkable, all of a sudden spring to life once you've squirted 10 watts up it (it takes a few moments to work out a tune).

See reviews here: http://www.eham.net/reviews/detail/483

I'll write a blog about it shortly since I've used mine as a vertical, a doublet and a loop. Bloomin marvellous they are!

For info, I've recently had an 8m whip in the garden with 9 radials. Just amazing. It does out-perform almost anything I've got but the trouble is they only handle up to around 200w PEP. If you are a QRO sort of person, get a big manual tuner :)

I have loads of pictures of mine on my website.

Cheers,

Callum McCormick

Nice comments on your web site!
I have a lot of wire am thinking of playing with but I am mostly playing with the old Curshcraft R-7 vertical. I miss the low G5RV for local nets and want to put up something else.

BTW your web site says you "just don't have the trees" now you need a house too??!! What happened <LOL> I have a house with two trees in the yard so something low maybe possible. Not 80 ft though thats for sure more like 30 ft if I am lucky!

Look for you on PSK31.

From: Dr. Ace Ratliff
Topic: 2896 Message: 2965

__, Hi All,
Does anyone have any info, experience, opinions, etc. about the MFJ-998,
1500 watt Intellituner. I am thinking about ordering one for HF operations.
BTW, (now I'm bragging) I recently got a mint condition Henry 3002 amp but I
haven't installed the 240 V AC wall socket yet. Unless I put up another
antenna I will not be able to run it at full output as my cushcraft 13 element beam is
only rated for a KW.

I agree with most of what Callum said -- I use the Icom
AH-4, and I've had exceptional results with it. Using 110' of wire
on it, I can tune all bands form 6-160 meters, with the exception of
3500-3700 KHz -- the wire is a half-wavelength there, so the
impedance is just too high for the AH-4 to match.

Of course, getting a good match -- "coupling" the antenna to
the coax -- doesn't necessarily guarantee a good signal -- on several
bands, my signal apparently goes straight up! 17 meters, in
particular, gets a great match, but if I hear anything there, it's
weak. A quick check using EZ-NEC shows my radiation pattern to
theoretically be almost straight up, with next to no signal in any
direction below perhaps 70 degrees elevation.

I believe the range of the AH-4 is from ~5 ohms to ~5000
ohms. Of course this is greatly simplified and not speaking to reactance.

> >and I've had exceptional results with it. Using 110' of wire
>
>Loop or sloper?

Level piece of wire. I have the AH-4 mounted on a 20-foot
piece of plastic pipe at the end of the house. The wire goes 72 feet
due south to a corner of the yard, then turns due east for another 50
feet or so. It's all at about 20 feet up.

You might like to try a pair and get an extra 3dbi gain? I built a pair for 2m and fed them as a stack, however the distance between them is probably a bit difficult for 6m though? I seem to remember mine are a wavelength apart..? I think you can squeeze this down to half a wavelength. Not sure.

Hi Dwayne,

No real cons, but it's not as good as a 5 element yagi. If you want to beat the yagi go with a rhombic antenna. Pros = good band width, quiet noise floor, easy to match, low cost, gain over a dipole, easy to construct, etc.

Fed at the bottom corner of a diamond a loop antenna has horizontal polarization.

If you hang it from a tower, you could use a single 1 inch PVC pipe spreader horizontal inside the diamond. I would put a PVC T connector in the center of the 1 inch PVC pipe spreader then attach a 1 inch PVC pipe from the tower to the PVC T connector to hold the antenna stationary.

"A vertically oriented horizontally polarized one wavelength loop antenna with the bottom of the loop 1/2 wave length above ground is a FINE antenna".

Do NOT put the bottom of the vertically oriented loop more than 1/2 wave length above ground.

The impedance of a Full Wave Loop antenna is theoretically in the vicinity of 100 ohms. That is why I use a 75 ohm "Q section" to provide a perfect match to the 50 ohm coax. My Loop antenna is flat 1:1 VSWR without using a tuner.

Here is How I Do It.

IMPORTANT - Connect the shield of a "Short Piece" of 75 ohm coax to one end of the loop antenna , Connect the center of the 75 ohm coax to the other end of the loop antenna. The length of the 75 ohm coax is most important. It will be used as a Q section.

To determine the length to use, Use this formula "Length in feet = 246 x VF / Freq in Mhz" VF = the Velocity Factor of the coax. So multiply 246 by the Velocity Factor of the coax , Then divide by the frequency .

If you use RG59 or RG11 with a Velocity Factor of 0.66 , For the 75 meter band the Piece of 75 ohm coax should be about 42 feet long , It doesn't need to be exact . RG59 and RG11 coax usually have a Velocity Factor of 0.66 , Foam dielectric coax such as RG6 might have a Velocity Factor of 0.81 or more.

Put a PL259 coax connector on the unused end of the 75 ohm coax, Screw a PL258 double female coax connector onto this PL259 coax

connector. Then connect 50 ohm coax to the other side of the PL258 double female coax connector, Use any length 50 ohm coax needed to reach your Transceiver.

Here's the only con I could think of, and it would not apply if the antenna was oriented horizontally. Vertically oriented it would have some (not sure how much) directivity.

You could construct the antenna and then spin it to check it's directivity. If you thought it had too much directivity (I don't think it will) You could make 2 antennas and switch between them.

Topic: 2975 Message: 2976

Tony, the reflector is the longest wire loop so it would have to be on the outside and the director on the inside. They would have to be spaced about .15 wavelength between the loops. If you try to draw it on graph paper you will see it is not possible to have them on the same plane.OTOH, I have seen loops on 6 or 2 meters stacked one above the other, possibly could do it for 10 meters, to increase gain omnidirectional.

From: Jason Buchanan
Topic: 2979 Message: 2979

My loop went down yesterday, snapped and broke on a corner.

Looking at it more carefully the plastic shielding looks to have done far worse damage than it would have helped. I should have used bare wire. 100 feet of either side where it broke the copper has a slight greenish hue, apparently due to trapping the moisture inside the plastic insulation. On 5 feet either side of the break it is black and nasty - so it had been corroding for quite a while. I have the same wire, but BARE, on other antennas that have been up for 5+ years, but the loop lasted only about 18 months.

Next time i'm going to opt for #12 bare wire. argh.

Sounds like you may be using the Wrong kind of
wire... Ever think of getting a roll of 14 Ga. copper
coated steal ?
Sounds like at this time you are using copper wire
that is intended for in a conduit. Not hung up in
the air.
BTW It is normal for copper wire to turn color in
the air. That will not affect the radiation of it .

I was using #14 flex weave with the plastic jacket. It was holding up fine except for the corners where there is the most tension. Not sure if copper coated steel would last any longer though unless I use a larger diameter pulley. I have a 1" pulley on the corner but I think a 3 inch pulley would be better as it would spread out the tension across a greater surface area.

My experience....with either a support line or antenna wire.....

You can not use too large a pulley....

Copper household wire work hardens, it is not designed for much more strain or movement than pulling it through a conduit and rarely touching it again. It is so easily damaged (nicks, work hardening), it often breaks when replacing a household switch or receptical. It shouldn't be considered for anything other than it was designed. Copper clad steel, on the other hand, it designed for communications lines and antennas.

My loop using stranded, coated wire has been up for 7 years. It has 2 splices that I remember. The ropes have broken multiple times, but the wire has NEVER failed. Still works great! I did replace the coax feed with open wire line, though. Very good antenna. Worked Clipperton a couple weeks ago with it barefoot from Michigan.

Thanks All
I have built the 6 meter loop and have it hanging on a wooden pole (old power co pole) in the back yard. I have one spreader in the middle made from 1 1/4" pvc.
I hung it at the top from a block of teflon with a V notch cut in it for the wire to hang in.at the bottom I built a Teflon terminal block to terminate the ends of the loop to and used a rubber bungee cord to pull it down and keep it tight.
I used rg-6 for my Q section and the SWR is Great over a Wide portion of the band!

From: Steve Holman
Topic: 2988 Message: 2988

Well I have had the loop up for a while. And it has exceeded my expectations to this point. In the contest this weekend I was able to work everything I could hear except for one or two mostly due to QRM from the contest. I will have to rework my supports this spring as they have gotten loosey goosey (technical word there) and the wire sags but it still communicates.

These Skywire things WORK!!

Oh pls don't abandon insulated wire for a loop. Like GREG, my experience has been very positive with insulated stranded wire. I have had mine up for 12 years and a couple times the ropes have worn through (I don't use pulleys), and about 4 years ago something caused it to sag and it got tangled in my chimney covers. Try as I might, I could not get it untangled so I pulled it till it broke. Doing that, I had sort of worn through a section of the wire so I replace it with 10 feet of non insulated wire and about 3 weeks ago, the loop broke where the splice was and when I examined it, the non insulated stranded wire was very corroded. I went back in with an insulated wire section. Now, this is 16 gauge stranded insulated wire I'm using. Not 12 gauge or even 14 gauge. I thought about replacing the entire loop due to its age but went back with the same 12 year old wire as it looks pretty good.

My loop is a full wave 80M loop at 50 to 60 feet up feed with open wire. I have 141 countries on it in the past 4 years since I started using the N3FJP software to track my QSOs. That's all bands. I have 25 on 80, 87 on 40M and 123 on 20M and a few on 15 and 10M during this sunspot LOW. And Worked all States several times - 49 on 40M alone. And I'm 100% QRP!

Hi all,

I had used bare #14 stranded copper-clad steel "antenna" wire from one of the well-known suppliers (not trying to keep secrets, I just can't remember from which I bought -- The Wire Man? Davis RF? "Jake's Place" (cablexperts)? 99% it was one of these)

Anyway, it was up about 5 or 6 years. I have taken it down now because the supports broke again and I haven't gotten around to replacing them. But the wire is still in very good shape.

Maybe it has more to do with the quality of the wire itself, and less with the insulation? I don't know. Just guessing.

For support-springs, I'm thinking next time of using the springs big trucks use on their air-lines hanging off the back of their cabs. I've seen them in two lengths, one maybe 2 or 2.5 feet long and the other about half that length. They feel like about the right amount of tension and they obviously survive outdoor weather in poor conditions --road salt, lotsa tugging-- quite well because they hardly ever break.

Has anyone tried them?

Hi,

I concur ... solid copper coated or not if properly installed is all but indestructible. I have put up any number of wire antennas and never have to special order the wire ... I go to an electrical supply store and get standard #14 gauge insulated wire. The only thing that ever deteriorates and breaks are halyards ... and there are tricks that can be used in these cases. You must properly terminate the wire in a good size smooth strain insulator ... so any movement is against the insulator and not the wire. This wire will easily hold 150 ft with a suspended feed line in the middle. If there is no suspended feed line you can easily go beyond 150 ft.. In the case of a loop the main problem is usually 'cutting corners' at the corners (no pun intended). One is tempted to use a single insulator and put the wire through ... sometimes to even allow it to move. This will always be the breaking point. On a 4 sided loop each side should terminate in its own egg (strain) insulator and there should be no movement of the wire at this join. The should only be a tensile strain (if that is the word).

I have a particular 150' length with feed line in the middle out at the farm that has been up there for at least 15 years ... tied between swaying branches of large trees ... there have been uncounted halyard breaks ...even a couple of feed line breaks ... but never a break in the horizontal wire.

From: Tim Folkenson
Topic: 2993 Message: 2993

I have been using my 80m loop w/TenTec tuner all winter with great reults. Yesterday I replaced my 22ga temp wire with a 14ga permenant solution. I am running 450ohm ladder line through the attic past all kinds of duct work etc. The system works well with a tuner (so I thought) until I hooked up the MFJ analyzer to find resonance,

The best SWR I get is 3:1 @ 100ohms. What's up with that? Should I run it through a ballun before the analyzer? Maybe run the ladder line to coax like a G5RV?

TIA,

Tim in MN KD0AHR

I, too, use the 14 ga. insulated electrical wire. I get mine from Lowe's when (if ever again) it is on sale. My 475-foot loop's been up for almost two years with no failures. My neighbor did have some pine trees taken down and, in the process, they let a tree get into the loop and it broke it, but only in one spot. That gave me the chance to inspect the wire and, though the black outer insulation showed some damage where it went through one of my insulators (I'm sure that happened when the tree hit the antenna), the inner plastic--next to the conductor--was still untouched. I did the best splice I could manage and it has stayed up fine for five months now, including during some pretty good thunderstorms.

I use PVC 45-degree elbows at most of the support points. That allows the wire to move within the elbow without causing undue friction on the insulation. See my site at www.n4kc.com if you are interested in what I did.

I have to use insulated wire since my loop necessarily runs through some branches, but the typical Lowes stuff seems to be holding up just fine.

I also use the 14 ga. insulated wire for a 135-foot doublet and it got hit by the same tree. It broke at the end, at the insulator. Very convenient! I was able to re-hang it on a higher limb. Sweet!

Tim, your first mistake was hooking up the SWR analyzer! You said it was working great but then you fooled around and found out you had some danged old standing waves. Sometimes ignorance is bliss! So long as you are feeding with ladder line or window line, and have a good tuner that seems to find a match in most places, don't worry about SWR.

Yes, a 4:1 current balun at the output of the tuner would probably make it easier to match at many places in the spectrum. Some would even argue that a 1:1 ratio would work better in spots, such as when the impedance falls very low. But if your tuner has been handling it on the frequencies where you like to operate, and you see no signs of heat within the tuner that indicates excessive loss, I'd ignore those pesky standing waves and OPERATE!

By the way, you should find that 80-meter loop to be an effective all-band antenna if you have a good external tuner and don't introduce too much coax into the equation. If you're interested, I have a couple of articles on my web site on this subject: www.n4kc.com.

I use 16 gage stranded that I picked up at a supply house. I have more problems with the line holding the antenna in the tree than I do with the wire. I have found that 50 pound test or greater, is cheap, effective and gives a bit when the trees sway. Several antennas up for more than several years with no issues. It is also relatively stealthy.

Okay ..... you have a 80m loop connected to 450 ohm feed line which in turn is connected to your Ten-Tec tuner. You are getting good results ... on more than 1 band 80 to 10 mtrs I would assume. I also assume your tuner matches the system to your radio (50 ohm output) satisfactorily .... (meaning the SWR at the radio is satisfactory).

You connect your antenna analyzer to make a measurement .... where do you connect it? on what frequency do you make the measurement ? and for what purpose (although you mention to find resonance) .. curiosity ??

Hi Tim,

As others have already said, just leave well-enough alone! ;)

It sounds as if your antenna is working as expected. All-band antennas will normally display a wide range of impedance values, and a wide range of reactances as well. You may or may not find they approach 50-ohms in one of the amateur radio bands. But that doesn't matter in all cases. This means you might expect many swr values as you scan across the amateur bands.

Of course, this doesn't answer your question, nor point out other questions you may wish to ask. Read on!

When does "too high" swr matter? Certainly *not* when you are using open/balanced line (such as the 450-ohm ladder line you are using). Why? Because the loss is so very low! In fact, it is almost not worth measuring. That means you can even have 50:1 swr on open/balanced line and not really care, because there is not enough to notice as you operate.

Coax is an entirely different animal! Most of us think 10:1 swr is usually too high on coax. But even then it depends how long the length is, because a 6-inch or 1-foot length still won't have much loss at 10:1 swr. But if it is 100-feet, the odds are the losses at 10:1 swr will be quite large and very noticeable.

So much for the transmission line.

What about the antenna?

Well, the antenna doesn't care about swr either. As the RF travels from the XCVR to the antenna, some of the RF is 'lost' inside the antenna, but that is our desired goal: RF 'lost' in the antenna radiates into the sky!

What RF doesn't radiate from the antenna bounces back toward the your XCVR (or transmatch if you are using one) and we call it the 'reflected' wave. When this reflected RF hits the XCVR/transmatch, none of the RF is 'lost' inside the XCVR/transmatch (it all re-reflects back toward the antenna). When the RF reaches the antenna, this all starts over again: some RF radiates; some reflects. Over and over until all the RF has escaped the system from the antenna. ... With one exception: transmission line attenuation, which can be thought of as the "heat loss" taking place inside the transmission line as the RF travels from one end of the line to the other.

And *that* is why the quality of the transmission line is so important!

If it is open/balanced line this "attenuation" is so small it is seldom worth worrying about, and therefore swr is equally unimportant. You do have to keep the line "balanced" however, or the situation needs to be reevaluated. Maintaining balance basically means keeping the ladder line a minimum clearance of a couple inches away from other objects, especially those that are metal or magnetic. Maintaining this clearance is not always possible, such as when going through attics and walls for example. If the line becomes unbalanced it will begin to radiate just like an antenna. If fact, it becomes an antenna.

When you use coax there are more variables to consider. A big plus of coax is you can route it just about anywhere; the downside is it is much lossier than balanced line. The condition of the coax is important (age, cuts, etc), the quality (attenuation loss at the frequencies you are using), and the total length used, are all important to consider. You weigh all these variables and end up with a total loss for your situation. Then you consider the swr on all the bands you intend to use this with, and look up the additional losses due to that swr.

The other thing to consider about swr is how it interacts with your XCVR/transmatch. If you use a transmatch, the XCVR is protected from any unusual swr because the transmatch transforms the impedance to something close to 50 ohms. Assuming you can 'tune' the antenna system, of course.

Sometimes the antenna system presents too high or too low an impedance for the transmatch to successfully transform: we can't get a 'tune' in these cases. Now you need to change something in the system if you are going to use this antenna on that band. But what?

You can try a different transmatch. These are generally most efficient when not pushed to their extremes, and when pushed beyond their extremes internal arcing or damage may occur inside the device.

You can try altering the geometry of the antenna too. Shorten it, lengthen it, angle it differently, change the angle the transmission line approaches it, change the height, and on and on.

You can also alter the length of the transmission line. Sometimes that will change the impedance presented to the transmatch enough that it can now 'tune' the system.

Questions:

What was the worse swr? What was the swr on each of the amateur radio bands you wish to use? Has your transmatch (aka tuner) been working fine?

All of which can be summed up with the popular phrase: if it ain't broke don't fix it ;)

I hooked it up in the shack to the ladder line. I expected to see 100ohms and wanted to trim the line so I get a dip in SWR within the Ham band range on 80m, 40m, 20m. I am going on the assumption that my old Tempo One will put out around 100w and I want every electron to leave my wire in the most efficient way.

My understanding of a tuner is that it does not fix an inefficient antenna, it just masks the symptoms. I don't have power to spare, so I want an antenna that resonates well where I tune most. That would be SSB 20m and 40m first; PSK 20m and 40m second; and 80m DX SSB third. I have had some contacts on 80m but find less CQ calling on 80m SSB than the other bands. My perception is that 80m SSB is more of a rag chewing arena?

Sorry if I ramble,

Tim

I've been using 14 gauge insulated wire I bought at
HomeDepot when I got my HF priveledges back in 1996.
I think it started out as a 500' spool. Seems I paid
less than $25 for it!

The only breaks I've had were not the wire but where my
heavy nylon cord (trotline string from a sporting goods
store failed after years in the sun) and abuse by the
trees that never seem to move together.
The wires I cut in 1996 for my original 17m and 40m
dipoles are weathered but still intact.

Recently (December '07) I picked up some 18 gauge aluminum
Electric fence wire from Tractor supply, after a little
over 3 months it's still holding up)

> My understanding of a tuner is that it does not fix an inefficient
> antenna, it just masks the symptoms. I don't have power to spare, so
> I want an antenna that resonates well where I tune most.

Hi Tim,

This is a common debate. Sometimes a heated one, hehehe. The correct answer depends on how you look at the variables and what you wish to use as your yardstick of success.

Point #1.

The antenna itself is usually very efficient. Once RF gets to it, the percentage of RF that escapes the system from the antenna is quite high. We're talking high-90% here, so it isn't usually the antenna that is the problem.

The antenna "feed point" can present a barrier however. This is true when the impedance is greatly different than the impedance arriving at the transmission line attached to the antenna feed point. If these are the same --or close-- the RF easily flows into the antenna, and it radiated efficiently.

If the impedances are greatly different values, then only a fraction of the RF will enter the antenna and the rest will reflect off the antenna feed point back toward the XCVR (or transmatch).

When this reflected waves reaches the XCVR (or transmatch) it will then re-reflect in the original direction toward the antenna.

Point #2.

Masking symptoms? I think I'd prefer to say it corrects the underlying situation. The only 'masked symptom' that the transmatch will fix is to remove reactance and transform the non-reactive resistance to that into which the XCVR may properly load.

That is all a transmatch does. Both are important, but they aren't occult goals or anything.

Point #3.

Resonance is only the lack of reactance. An antenna does not need to be resonate to efficiently radiate RF. This is fortunate because an antenna can only be resonate for a single frequency, and that would make for a severely limited ham radio antenna!

Don't worry so much about resonance. Now if you care about the shape of the RF envelope being radiated by your antenna, *that* is a valid reason to consider the geometry of the antenna.

The Forgotten Point.

Transmission line losses (attenuation) is the real point here. The RF will bounce back and forth between the XCVR (or transmatch) and the antenna until the RF either escapes out the antenna --which we deem good-- or until it is absorbed by the transmission line as heat --which we deem bad.

Therefore, your time and efforts are better spent worrying about ways to improve your transmission line than trimming the antenna for perfect resonance. (And recall, the antenna will no longer be resonate once you spin your VFO to a new frequency.)

So all of this is a balancing act. Remember to think about the antenna *system* as a whole, and don't focus too much on any one part of that system, and you'll be off to a goo start.

Topic: 2993 Message: 3005

I got confused when you said that the SWR is "3:1 @ 100 ohms."

Did you mean the SWR is 3:1 expressed with respect to a Zo of 100 ohms? Or did the SWR meter read 3:1, and the (real? magnitude?) part of the impedance was 100 ohms?

It is important to realize, an SWR meter does not measure SWR. It effectively measures impedance. Then it calculates what the SWR would be, assuming some nominal reference impedance. Virtually all SWR meters refer to a 50 ohm nominal impedance. This might not be what you want.

Let's say you have a perfectly matched 450 ohm ladder line. Hook almost any antenna/impedance analyzer to it, and it will show what looks like a poor 9:1 SWR, even though it has a perfect match and has no standing waves! You'd need an SWR meter calibrated to 450 ohms rather than 50 ohms; or use a 3:1 transformer to transform that 450 ohms down to 50 ohms. Otherwise, the SWR number is meaningless for that ladder line.

Unless your environment is 50 ohm coax, it is better to look at the complex impedance than the SWR number.

Even then, you might not care what the impedance reads, especially if you have ladderline and an antenna tuner and you are measuring between the tuner and the antenna. But it is helpful to tell you when the antenna is resonant: when the impedance's imaginary part goes to zero.

Hi Tim,

No problem. First, lets ease your anxiety about the efficiency of your antenna/system ..... it is just fine. The efficiency of your antenna first depends on its size (in relation to frequency) and height above ground. Your antenna is a full wavelength on 80M and it will be very efficient on all bands 80 - 10 mtrs (height is then only thing that will make it more efficient ... you didn't mention height).

Having said all that, the rest of the system (feed line and tuner) serves 2 objectives; the first objective is to feed as much RF to the antenna as possible and the second objective is to provide a workable impedance load to your transceiver. Generally speaking there are 2 ways to achieve this. The first method is to design the antenna so that it represents a specific impedance at a specific frequency. Then carefully match that impedance to a feed line (very often coax is used) which usually results in a mono band antenna. Here the efficiency of the 'system' largely depends on keeping the SWR low on the coax feed line as coax is very susceptible to dramatic increase in losses with SWR.

The other tack is to largely ignore 'resonance' and the careful matching of the antenna to the feed line and to use open wire feed line instead of coax. The reason is that open wire feed line will not loose much power due to high SWR on the feed line. The objective of this system is to make the particular frequencies of interest (you carefully pointed out frequencies

of interest to you) tuneable .... eg will your tuner at the operating position convert the impedance at the end of the feed line to 50 ohms resistive .... the impedance your Tempo One likes to see. The SWR on the feed line will cause the reflected power to move back and forth in the feed line finally putting most of it into the antenna as radiation ... very little will be lost in the feed line.

Your antenna system is the second kind ... which by definition will represent a great range of impedances depending on frequency and feed line length. The result is that measuring the impedance at the end of your feed line can serve only one purpose .... to see if it is within the range of your tuner .... eg .. it might give you an idea of why your tuner is having difficulty producing that 50 ohm load for your radio. In summation then, you need only measure your SWR at the output of your tuner .... ideally it should be 50 ohm no inductive or capacitive reactance. If you can't achieve this at your favorite frequencies then you might look at adding or trimming feed line etc..

Thanks for all the good info. I will leave things as they are. My last question is about directing a loop and DB gain. I recently heard about Hams tilting their loop and/or adding a 2nd loop to increase the gain and/or direct their signal in a specific direction.

I am on a suburban lot with plenty of trees so wire antenna(s) are my best way to stay under the radar of the neighbors. I was thinking of either a 20m loop or a wire Yagi pointed at Europe using coax as a feed. Multiple loops? Any thoughts about my crazy idea?

Hi Tim,

You can certainly make wire beams if you wish. Obviously you would be using fix-orientation as you describe. Height, size, and orientation should normally be considered when thinking about what part of the planet your antenna is likely to "illuminate." One of the best sites I know of to start reading up on antennas, and that includes various directional antennas, is offered by L.B. Cebik W4RNL:

http://www.cebik.com/

When you get the opportunity to order some books, I'd recommend the following:

Practical Antenna Handbook by J. Carr

And the two ARRL books to which many people will refer you over the years (you can often find older copies at hamfests, and any in the last 5 years will certainly be fine; maybe even 10-years old):

ARRL Handbook
ARRL Antenna Book

I haven't checked the prices of these lately, but I suspect they are close to $40 each. The newer editions of the ARRL books come with a searchable CD-ROM which some people like. In some cases (all?) that CD-ROM also has some small software programs that you may find of interest. I'm sure the 'book store' section of the ARRL web site would have more information (http://www.arrl.org/)

Hi Tim,

Not crazy ... I just sent a description of a vertically oriented loop antenna system with a second element that I used many years ago (cubical quad). At that time I used bamboo spreaders etc ... however similar antenna can be built from light wire and suspended from trees .... here is a copy of what I sent on the other message list:

As with most things when you go big everything is magnified .... a quad for 20m is approx. 17' per side. I arranged the spreaders so they would be on a 45 deg angle to either the vertical or horizontal plane. The distance from the center to each corner is exactly 12'. I tied on small metal fittings to the ends and spread thin flexible braided type copper wire around the 4 corners (approx. 68' total) ... I fed the center of the bottom horizontal portion with 72 ohm balanced line. The 72 ohm balanced line (they don't make it any more as far as I know) came down to the shack and a 1:1 voltage balun (made by Heathkit from air-dux coils).

It was a perfect match ... and the antenna will take any legal level of power you would wish to put to it.

I used approx 6' to 8' for an aluminium boom. I used a second loop as a reflector ... and tuned it with a piece of open wire line for maximum front to back ratio. I later mounted a second set of loops within the first loop for 15 m and fed it from the same feed point with the same feed line. I never noted any deterioration in performance.

The only maintenance problem was ICE .... the antenna was very gud in the wind, but if there should be freezing rain with a build up of ice load the whole thing will droop like a wilted flower. The other problem was general weathering of the bamboo ... eg getting dry and brittle over time. The whole thing is quite light.

The spreaders in this arrangement are not under much tension. I used home brew flanges at each end of the boom to clamp the 4 bamboo poles for each loop. The tricky part is building this thing and then getting it up there. My 30' tv mast was made of 3 pieces that would nest together. I could build and adjust the antenna on the top of the 10' piece then push it up by hand. the bottom of the mast sat in a smooth cup on the base ... and the guys were attached to rings that allowed the mast to turn. so the only thing holding the antenna from turning was the friction in the cup at the base. The 2' pipe wrench was more than enough to rotate the whole mast/antenna assembly.

The quad worked very well on 20m at 30' height. A friend of mine had a quad on a 60 ft tower (a commercial quad ... GEM quad) and it was exceptional.

This is a description of a Quad (2 loop elements) I once built using bamboo spreaders. It could easily be hung like a 'sheet' between two supports. A second 'sheet' would be hung behind it about 8'. You feed the center of the bottom of the first loop and you tune the bottom of the second loop for either maximum gain or maximum front to back ratio. The wire loop is 17' square and you could feed the bottom of the loop with coax. It would be for a single band ... but will guarantee you dx contacts hi hi The higher the better ... but if you can get the bottom part of the loop up at least 10' ... with the top at 27' it will work vy well.

If you are looking at wire antennas, there is a book you should take a look at. It's "The Easy Wire Antenna Handbook" by Dave Ingram K4TWJ.

I believe the book is out of print, however copies turn up online frequently.

This isn't an antenna theory book. It's pure cookie cutter. For each of the antennas he even provides a table with the antenna dimensions for the various amateur bands. You'll have to look elsewhere to find information on how each of the antennas really work, but this book still belongs on any wire antenna builders bookshelf.

From: ira_ira_ira
Topic: 3011 Message: 3011

Hi, I want to build SkyWire, but have only space 20x10 meters so I was thinking to kinda fold this antenna to make it longer. Here is a little picture of antenna I have in mind. This antenna is only for receiving NOT for transmittion.
http://ph.groups.yahoo.com/group/SkyWires/photos/view/c093?b=1

There are two major questions I have conserning this antenna:
1. What is better - to have it shorter but single square or to have it this shape but longer?
2. As it's receiving antenna, and planned to be fed by 10m 75om coax do I really need balun there?

Thank you.
Yury

The only possible reason for the added linear loading stubs is to achieve resonance at a particular frequency which may be useful when using the loop for transmission. Resonance is usually not necessary or desirable in a receiving antenna. The efficiency .... or at least, the capture area is related to the circumference of the loop and not the length of the wire. The capture area is related to area ... 200 mtr sq. and not how much wire you use e.g. 2 or 3 turns or added stubs.

>2. As it's receiving antenna, and planned to be fed by 10m 75om coax
>do I really need balun there?

>Thank you.
>Yury

A loop is a balanced antenna and coax is an unbalanced feed line. This means that direct connection of coax causes transmit current to flow on both the inside and outside of the shield (radiation). In the case of a receive only setup the reverse happens .... that is signals that are picked up on the outside of the shield (desired and undesired RFI) find their way to the inside conductor and go to the receiver. A balun helps in both cases. For a receive only antenna I would recommend a simple RF transformer wound on a powdered iron core. This would provide broadband coupling with maximum isolation for the shield. Such an antenna/feed line would make an excellent HF system.

3014. Delta match to help feed my loop?

Yahoo group: SkyWires
Date: 2008-04-17 20:06:02 UTC
From: Bruce Conner
Topic: 3014 Message: 3014

I've got my horizontal delta loop back up in the air after the winter weather took it down and all's mostly well, except for one thing. It seems to dislike 30 meters, no matter how I twiddle the knobs on the tuner.

The antenna is a horizontal triangular loop (corner fed) with about 290 feet of wire in the loop itself and about 100 feet of feeder made from the same 14 ga insulated wire. The ladder line spacing is 3 inches, and in fact it is just an extension of the loop, there is not joint out at the antenna, I just ran the spacers up the doubled line. It's all one piece!(that was a job)

Anyway, I know the usual culprit for this sort of thing is the feed line length, but I was wondering if I made a delta feed section into the loop instead of an abrupt change from the 3 inch ladder to a 60 degree angle at the corner of the loop if that would help me get a better match.

It does tune quite well on everything but 30, so I suspect a resonance issue of some sort. If I have to fiddle with the feedline length, I have to, but if there are other things to try first, why not?

Can't take any length off unless I want to move my rig outside! ;')
Might be able to add some. I wish I could make a stub that I could
clamp on without breaking the wire. Hmmm.

3022. Loop Configuration Question

Yahoo group: SkyWires
Date: 2008-05-08 12:25:11 UTC
From: Jason
Topic: 3022 Message: 3022

Hi All,

I moved to the country and am trying to configure a loop that does not seem to be working for me.

Here's the break down:

a) 272' of stranded 12 gauge wire in a relatively rectangular shape.

b) Van Gorden Antenna Center Insulator connects the 12 gauge wire in a tree.

c) 450 OHM 14GA Van Gorden Ladderline connects to my Insulator on one end and connects to a HI-Q 4:1 Balun on the other end.

d) From the 4:1 Balun a coax run goes into my shack on a Kenwood TS480SAT rig. (auto tuner)

I can tune just fine on 10, 15, 20, 40 meters! (even 160 and 6 meters tune at certain locations) Audio and SWR are perfect.

However, I cannot tune any higher than 3.800 on 75/80 meters. I have cut down the ladder line and no change. When I cut down the ladder line I tuned in the other bands perfectly. Ladder line sits at about 93 feet in length now. I tried cutting down further and I ended up taking out all the bands, so I reached the limit I believe. I cut back the last piece cut and back to where I was.

I thought maybe the hardware store made a mistake and my 12 gauge wire was short. So I added 25 feet to it in the middle. It actually made 75/80 meters worse, as it didn't want to tune above 3.700. So I reverted back.

Any thoughts on what is happening? I seem to be stuck at 3.800. I don't know if this frequency, exactly, is telling me something? Any suggestions would be greatly appreciated!

Hi,

First, your antenna system works very well with full coverage of
10,15,20,40 mtrs and 80/75 up to 3.8mhz ! Apparently the tuner in the
TS480SAT has an issue with 75m and the particular impedance it sees at that
frequency. You mentioned 272'. If you work backwards from the formula
1004/F it would be resonant at 3.7mhz while adding 25' would work out to

3.4 mhz ... Perhaps reducing the original 272' might be more to the tuner's liking.

putting an antenna analyzer on the end of the balanced line would be useful ... (I may get one some day hi hi).

Thanks for the response. My goal is to get on nets that are between 3.932 and 3.952.

Do you think shortning the 12 gauge wire would do the trick? I'm sitting right at at 270'....

We did put an analyzer on the line and it confirms what the tuner is saying. VERY high SWR readings up near 3.9.

Thanks again!

I always use a bit shorter wire - about 240 to 260 feet. I seem to have a better time matching on 80M and higher. But I also don't have an issue with matching at 3.9 or so. I use a Kenwood TS 830AT and a MFJ Versatuner V

Since you are using balanced line the high swr won't cause much additional loss (transmission line attenuation) as it would when using coax. That is one of the big reasons swr receives so much attention these days... high losses on coax. But that is almost never a concern with ladder line, or open wire, etc.

However, the other side of high swr is the impedance presented to the XCVR (or transmatch when used) and when that falls outside the range the device (XCVR or transmatch) is capable of matching (too high or too low) you can't use that antenna configuration without some modifications.

The 'modifications' can be all kinds of different things.

Perhaps the simplest would be to try a different transmatch. One that has 'bigger bits' -- those internal to the XCVR are well known to have rather small matching ranges.

You have already tried changing the length of feed line, and the loop itself. Both can work, but as you have observed they effect all the other bands too. Some people carry extra lengths of transmission line. In your case, you might go back to what worked for the majority of bands, and then play around with adding transmission line to get that last band.

Or, you could use the analyzer to see how much reactance is present on the 'bad' band and then make an insert to add in line when trying that band. For example, if you find it is adding 100 ohms capacitive reactance, make a coil you can plug in line that adds 100 ohms of inductive reactance. Or vice versa.

Or, you could add a LC-match and accomplish the same thing with greater flexibility. But these days it might be simpler to get the bigger transmatch.

Hi,

I would give it a try. An SWR of 3.9 doesn't really give you much information on its own. It appears that the tuner is unable to compensate for the reactive component that appears at the load. Since this portion of the band is of special interest you should be able to find a combination that works. Using the 1004/f formula the circumference at 3.95 is about 254 ft or almost 20ft less than what you started with. It won't hurt to give it a try ... after all you want to use that portion. Good luck ... let us know how it works out.

Looks like taking out 12 feet did the trick. I can now tune where I
want and the other bands appear to be working as well! I'll do some
testing this weekend and we'll see how it works out.

Thank you all for your responses!

Congratulations .... I'm glad u were able to get it working on the band section of choice. Your experiment is actually quite edifying ... removing 12' from the 272' loop made the difference between working and not working on its fundamental band.

Jason- congrats on your loop. You will really like it once you get it working well. I would not trust the HI-Q balun. Have seen and heard of issues with them - I won't expound any futher than that right now. I have almost the same loop, and have fed it with coax all the way to an external tuner (Ten Tec 229), and have fed it with open wire line to an old Johnson Matchbox. Both worked well. No Balun on the coax feed. If you DO want to use a remote balun, as you are, you might want to go to the DX Engineeering web site, and read the material there on Baluns. Very educational.

Let us know how you make out.

Sounds like a nice setup, wish I had that much space to work with.

Have you tried another tuner? Sometimes a manual tuner can do better
than an autotuner.

That's only an average of 68' per side if it were square, smaller than most houses, how small of an area do you have?

For baluns, check out: http://www.balundesigns.com/servlet/StoreFront

He gets great eham reviews, is reasonably priced and he'll discuss
your needs. Looks like a great product. I don't own one yet, but
will soon.

Wish I had room for a loop, managed to get away with a doublet on
the apartment roof, soon to be fed with ladder line.

It sounds like the load seen at the transmitter is outside the range of the auto tuner. MFJ makes an auto tuner range extender that could be added to help the inernal tuner match the load. Good Luck with the loop. I know you will be pleased once you work thru this problem.

I moved to the country and am trying to configure a loop that does not seem to be working for me.

Here's the break down:

a) 272' of stranded 12 gauge wire in a relatively rectangular shape.

b) Van Gorden Antenna Center Insulator connects the 12 gauge wire in a tree.

c) 450 OHM 14GA Van Gorden Ladderline connects to my Insulator on one end and connects to a HI-Q 4:1 Balun on the other end.

d) From the 4:1 Balun a coax run goes into my shack on a Kenwood TS480SAT rig. (auto tuner)

I can tune just fine on 10, 15, 20, 40 meters! (even 160 and 6 meters tune at certain locations) Audio and SWR are perfect.

However, I cannot tune any higher than 3.800 on 75/80 meters. I have cut down the ladder line and no change. When I cut down the ladder line I tuned in the other bands perfectly. Ladder line sits at about 93 feet in length now. I tried cutting down further and I ended up taking out all the bands, so I reached the limit I believe. I cut back the last piece cut and back to where I was.

I thought maybe the hardware store made a mistake and my 12 gauge wire was short. So I added 25 feet to it in the middle. It actually made 75/80 meters worse, as it didn't want to tune above 3.700. So I reverted back.

Any thoughts on what is happening? I seem to be stuck at 3.800. I don't know if this frequency, exactly, is telling me something? Any suggestions would be greatly appreciated!
Try shortening the loop slightly.

Hello All,
I have an 80 meter loop and have used 40 meters loop, coax and twin lead feeds. Has any one tried a closed full wave loop with a single wire feed against earth? Like a classic Windom dipole.
My 80m loop that is 1:1 at 3.8 MHz without tuner but fairly low would not tune in band with my LDG Z100. It would tune on 1.85MHz but was 20DB down on an inverted L. It did tune on 7 and 14 but no time yet to test further.

How high were you planning to put the loop, and how were you planning to feed it? What is your goal - DX, local or?

A horizontal loop fed with a single wire (or shorted feed line) will
be a vertical antenna with a large capacity hat. Unlike the Windom
there will be no horizontal component. The reason is that the loop is
symmetrical while the Windom is asymmetrical (off center fed).

3054. Maltese Cross loop antenna

Yahoo group: SkyWires
Date: 2008-05-29 00:35:45 UTC
From: Jonathan Helis KB5IAV
Topic: 3054 Message: 3054

I've read in a couple of other ham forums about hams pulling in the corners on a loop making a shape similar to a Maltese Cross.

Right now I'm running an attic mounted 25ft by 5ft open loop(basically a dipole bent into a rectangle) fed with Radio Shack TV twinlead, an MFJ balun, and an LDG Z-10 Por Autotuner. It loads on 60-10 and sometimes will load on 80, but I've never made a QSO down that low.

So far it seems to work well making contacts to the northeast and southwest, working mostly the New England states, and I've worked France, Mexico, Cuba, and Nicaragua on it.

The only complaint I have is it's very noisy, which I know is partially due to it being in the attic. I was wondering if anyone had tried a Maltese Cross configuration of a closed loop. I was thinking of doing that so I can get more wire into the space.

I went with the open design because I thought it would have a better chance of getting on 40 than a closed 60 foot loop would. I may be able to get another 20 or 30 feet of wire up there if do a Maltese Cross, which would give me around 80 feet for a closed loop.

I'm wondering if that might work at getting to where I want to be.

Thanks.

How are you feeding it, Willie? If you use ladderline and a tuner you shouldn't need to care about the specific SWR, and by nature I've found it to be "effectively" a broadband antenna. I wouldn't in a million years feed it with unbalanced line, however.

I agree with Chuck,do it right with balanced line and tuner and it's a marvelous all band antenna.I don't know where all the talk of coax and baluns started with loops and doublets but that defeats the purpose of these great antennas.If you have a problem on 1 or 2 bands just prune the ladderline until the problem goes away.

Forget one button band hopping,tune the tuner and hear and work things you have been missing with the compromise antennas.

Hi
I have a 80M loop thats my favorite antenna for all bands and I agree fully with W0OXJ`s statement.
I use a AG6K " balanced balanced tuner" and it tunes every possible band. (except) 160M
Tuning is quick and takes only a few seconds.Forget the baluns and the coax.

Every time I turn around, hams are bashing the use of coax....

Yes, on long runs, coax is not a good option.....

My first antenna was a loop a little longer than 80 mtrs. Worked every thing I could hear with
just 35W. There was no difference in what I could hear/work between coax and ladder line...coax tuned a little better on the higher bands, ladder line tuned a little better on 40, due
to the error in loop size, both had issues on 80. The catch....was only about a 30 foot run....

When I convince the city to let me put a loop up again (more of a Maltese cross this time to
try to get down to 160), will again be a short run and will be coax.

On short runs, I feel that the removal of any chance of RF in the shack makes coax a much better option....and it works just fine....

Just my $.02.....with the economy the way it is....that makes it more like $.002

Hi,

Another agreement. If you are planning to use either a loop or a dipole as a multi-band antenna there are basically 2 methods of doing so. The first method is to place an automatic antenna tuner/coupler right at the feed point .... which couples the antenna to a coax feed line. The second more common method is to bring the feed point down to the station with a balanced feed line (low loss) where the impedance is transformed to an acceptable value (to your transmitter). The second, with the parallel balanced feed line is the by far the most commonly used method.

Rule #1 is that the physical dimension of the loop is at least 1 wavelength at the lowest frequency to be used.
Rule #2 is that the feed point is connected to the transceiver with good quality balanced feed line.
Rule #3 is that an antenna tuner is required to convert the impedance at the end of the feed line to the 50 ohm impedance of the transceiver.
Rule #4 is the conversion of the balanced feed line impedance to the 50 ohm unbalanced input of the transceiver takes place as close to the transceiver as possible.

problem #1 The antenna tuner .... the majority of antenna tuners hereto generally available are designed to convert impedances from one unbalanced source to another and are generally capable of a limited range of impedance transformation.
Problem #2 since antenna tuners are generally UN_UN the practice has been to use BAL-UN transformer (balun). Further, there is a practice of placing this balun a distance from the tuner ... further complicating the problem.

Very often when you find you are unable to tune/match a portion of a band the problem is simply limitations created by the antenna tuner and balun. Trimming the feed line doesn't improve much except perhaps bring the end impedance within the range of the tuner/balun capablility. Don't get me wrong there are feed line lengths (sweet spots) that provide the maximum efficiency (measured in different terms ... another story).

I would say that the majority of the problems of tuning particular band portions are avoided by eliminating the use of a balun between the feed line and the antenna tuner ..... and using a balanced antenna tuner. In this arrangement the balanced antenna feed line comes into the shack right next the operating position and the balanced antenna tuner converts the bal-un and converts the impedance directly. It is well worth the effort in making this arrangment.

There are 2 key objections to this, 'feed line radiation', and difficulty in dressing the feed line. The first is a myth as properly dressed balanced feed line is as immune to picking up RFI and radiating as a good coax installation. The second is of course valid. It takes more thought/planning and work to make a proper installation ... but as I said, 'it is worth it'.

I have done comparative experiments and give you one as an example.

I have a large balanced antenna fed with 450 ohm balanced line which I bring right into the shack. I have 2 side by side antenna tuners. The first is a good quality UN_UN tuner with a 1:1 Balun. The first problem is that that it will not match the transceiver on all frequencies on all bands (keeping the power to 20W output). If I increase the power much beyond 20W (on some frequencies) I notice added tuning 'skittishness'.

I switch the balanced feed line to my low power balanced tuner (Z-match) ... I immediately have smooth (un-skittish) tuning on all frequencies and can easily run full power (100 watts for me).

I have mentioned transmitter power level. The reason is that at some particular frequencies the balanced antenna tuner handles the impedance transformation with high RF voltages. These voltages may be within the tolerance of the tuner at 20 watts output but move outside it's tolerance when the power is doubled. The fact of life is that an antenna/feed line/tuner system may cover all bands at 20 or 100 watts but be quite limited in coverage when you run 200 or 1000 watts!!

If you are a QRP operator then it is quite easy to operate all bands, all frequencies with a single antenna. But, difficult when you run QRO.

You'll never get them all. The spammers keep creating new phoney names. And they share your address with spammers.

The only solution is to set the group default to "moderate." Click on "delete as spam" when you get a spam message.

Then, you can set people to "unmoderated" individually as you get to know them and they can post without moderation.

Sorry, this is sad but true.

Unfortunately the group owner never gave the moderators that option, it HAS been gone over and over too many times to want to get into again so we just ban them as they post. But because of this problem there was another group started called LoopSkyWire. As of right now it has 78 members and the list owner has given the moderators more leeway in this respect to guard against this type of thing happening; I'm sure there'll be some that slip through but not as many as do here. If you're so inclined why not check out that group too, it's just as friendly as this group and knowledgeable group of people too.

3071. Lock or run free on insulators?

Yahoo group: SkyWires
Date: 2008-06-05 03:04:38 UTC
From: Paul
Topic: 3071 Message: 3071

It has stopped raining for two days in a row so I am itching to put up wire. My Plan is a 40M loop of bare wire up 40 feet . Depending upon which formula I use, I come up with 137 to 143 feet. I plan to run 450 window line from a close to middle side leg to a 4:1 Balun and short (10 feet or less) run of coax to shack/tuner. The loop will be in a rectangle pattern with the narrow widths at 30 feet and the long ends to be determined.

I hope to use in on 40M - 10M. I'm guessing it won't serve well on 80M.

Questions:
I have the space to add about 20 more feet over all (10 feet per long leg length). Will I gain anything or should I keep it closer to the shorter formula 40M length?

Is it better to "lock" the insulator at a fixed distance on the wire or should I let the wire slide free?

If I lock it, I was thinking of attaching an extra short length of wire through the insulator for increased wear life.

If I lock it, should I just twist the extra wire on or solder it. With solder I'm concerned about creating a "hard" spot where the wire will bend back and forth, fatigue and break. If I twist it I'm concerned that over time the electrical connection might cause grief. I could twist and wrap with good quality outdoor electrical tape.

What is the best way to manage the wire at the insulator points?

Thank you and 73,
Paul

Just checking but wouldn't the matching section, 246*.66/50? That
would 3.24 feet for 6 meters? Just checking my math..

I've sent in an answer but probably didn't use the correct email to mail from. But in a nutshell, lock the insulator and don't solder anything. If my message doesn't get by the moderator, I'll post the details.

Jim,
Your message below is all there is. I'm wondering about how critical the length is - given that I hope to run it 40-10 (80 if it will tune) with ladderline to a 4:1 to a auto tuner? Depending on which formula I use, I come up with 137-143 feet for the low end of 40M.

I can go with longer wire (about 20ft, 10 per side) and get closer to the support masts or I can use more line and suspend the antenna further out from the poles. I might be able to bring the poles in so they are closer to the rectangle of formula size, but I don't have a lot of altitude because of guy line anchor placement and angle.
Paul

Hi Paul,

I'd probably first try keeping about a foot or two distance from the loop and the supporting masts. Other than that I'd go for maximizing the area inside the loop.

I'm with you. You're going for a multi-band antenna, using very low loss line with a transmatch. I'd not worry about small length differences at this point.

That said, it is always possible to hit a "bad spot" so if you find it does *not* work, then alter either the length of wire in the antenna wire or in the length of the transmission line.

Also, scan through the frequency ranges of interest with an antenna analyzer if that is possible. Then you know what range of complex impedances you are asking your transmatch to transform for your XCVR. If there are problems this is often useful information.

Good luck and have fun!

Dave,

Sorry. I'm the owner of the group. I killed my exemptfromlife account
because of too much mail but I thought I had granted you guys all the
privileges you needed. Sorry.

I had gotten out of the hobby back in 2004 or so and now I'm starting
to get back into it. I tried to get my account reactivated, but the
yahoo automatic activation wouldn't recognize me.

If you have any suggestions, I'd be happy to try them.
thanks

Hello Kurt,

IMHO there are too much SPAM messages in this group; almost every day.

The new Yahoo-group 'LoopSkyWire' is without SPAM and has more than one moderator. Files etc. have already been transferred.

3087. Moderators, here's how to fix the "spam" problem

Yahoo group: SkyWires
Date: 2008-06-21 16:18:33 UTC
From: eudamac3
Topic: 3087 Message: 3087

A suitable replacement group has already been formed.

Any moderator can change this remaining group's description. Do so, removing the picture of the antenna, and simply replace it with text saying:

"This group's creator, due to a technical glitch, can no longer prevent spammers from joining. Therefore, this group is no longer an active discussion group for the subject in the title and is going to be taken over by spammers until Yahoo shuts it down.

If you are seriously interested in SkyWire antennas, please join our new group at:

http://groups.yahoo.com/group/loopskywire/

This won't stop spammers from joining this group - but it WILL stop people from joining the group, expecting it to be useful.

Frank

You can not eliminate spam - it is not possible. It can be minimized, but not eliminated.

For instance, your AOL account sends a piece of spam each time you use email. But being a AOL user, you obviously missed that.

> a 1:1 or a 4:1?

Ultimately, I think the answer depends upon the matching range of your transmatch as compared to the upper and lower impedances of your loop.

A balanced transmatch would be best. Few of us have one however.

My real-world druthers are to use balanced line to feed the skywire --horz. loop-- if you can use it, the balanced line has extremely low loss, and that may be important when feeding any antenna across multiple bands. Then to use a 1:1 current balun where the feed line goes through the wall. As opposed to simply smashing the ladder line with the (vinyl) window. (Yes, guilty; I have done that. ;)) But depending upon your transmatch that may not always allow an impedance match.

If not, then the next most likely candidate is to replace the 1:1 balun with a greater ratio balun, of which the 4:1 is the most common. These are generally the baluns found in most commercial transmatches. These are voltage baluns.

You might ask around about the hybrid balun discussed in QEX several months ago. I haven't heard much about it, nor have I tried one myself. The details are fading in my mind, but as I recall it was a voltage and current balun in series with one another. Perhaps someone reading recalls this better than I?

That's my 2-cents. Back in my hole! :)

Hi,

Very interesting antenna/feed system. In many ways it looks like the commercial system we used many years ago when I worked in the Arctic. Our horizontal loop was actually formed into a Rhombic antenna with a resistive termination at the far corner opposite the feed point. The losses are very low .... almost an anti-climax to hook a 5 watt transmitter on the end hi hi.

>
>thanks

A lot depends on where you want to put it (sorry for the korny start hi hi). But it is true. You are starting with a balanced antenna feed point way up there which ultimately is to be connected to an unbalanced output on the back of the radio in the shack. In fact, you may choose not to use a balun at all.

Generally speaking baluns are devices that work best at low impedances and in situations where you want to eliminate currents on the shield of coax cable that results from connecting it to a balanced antenna or feed line. Baluns that transform impedance as in a 4:1 balun are generally more susceptible to 'wonkey' behaviour .... especially when subjected to high impedances and substantial power.

So, If you are building a skywire for a single band it is quite possible to feed it directly with coax as the impedance mismatch will be low. However, there will be antenna current on the outside of the shield and a current balun, 1:1, located right at the feed point is a good idea. The 1:1 current balun can simply be a coil of coax feed line (20' is considered adequate) at the feed point.

However, most operators want their skywire to be a multi-band affair .... after all, it represents a lot of work putting it up ... the least it can do is serve as a multi-band unit. The feed point impedance is a close match to the coax feed line on the band for which it is designed, but the impedance varies widely up and down (mostly up) as you switch to other bands. It is possible to simply leave the coax feed line in place and match it at the point it meets the radio (using a coax transmatch). It will be possible to keep the radio happy but the efficiency (the amount of power that actually gets radiated from the antenna) will drop dramatically. You will still make contacts .... but the ERP Effective Radiated Power will be rock bottom.

So, if you build your skywire for 80m and feed it with coax (with or without a current balun at the feed point) it will operate very efficiently with your 100 w transmitter. As you switch your transceiver to other bands and tune the coax to match the radio you will have the radio happy but in

effect you will now be QRP (still feeding your 100 w to the system).

For many operators the solution is first to drop the coax feed line and to use a hi efficiency balanced feed line. The actual impedance of the feed line is not that important ... eg 300, 450, or 600 ohms is neither here nor there .... since impedance matching is not a consideration (since impedances of the antenna can be anywhere from 10 to 3000 ohms) what is important is its efficiency ... eg ... if the feed line is carrying a high SWR of say 20:1 the amount lost in the feed line (converted to heat) is low enough to be acceptable .... certainly nothing like the loss if the feed line were to be coax.

Now, somewhere along the route between the antenna and the radio the balanced feed line has to be transformed to balanced feed at 50 ohms impedance. This can be done with a single device (a balanced antenna tuner) or more commonly 2 devices, a balun and an unbalanced antenna tuner. The latter combination is the point where most of the problems arise. Most coax antenna tuners have a limited range of impedances they can match (eg tuners with coax in and coax out), and baluns 1:1 or 4:1 are susceptible to 'wonkey' behaviour when used at high impedances ... eg 1500 ohm balance to 50 ohms unbalanced. The manifestation of the problems (symptoms) are particular frequencies within certain bands where you experience inability to match to the radio, or you get flashover at some points when you apply power.

However, with the recent popularity of mult-band skywires there has been a resurgence of balanced antenna tuners. They are actually quite easy to build .... a simple L-match across the balanced feed line which then feeds a simple current balun at the output to the radio.

So, Balun or not Balun .... may not be the question.

Jim, VE3CI

> it is a heath kit Sine Square Audio Generator what is it what does it do

It generates sine and square waves. In other words, it is an oscillator, with both sine and square wave outputs.

The Heathkit IG-18 (if that's the one you got) was an excellent audio oscillator in its day. There were some improvements you could do to it to make it top-notch, and its performance is still no slouch today.

We used one for all our audio testing including annual FCC tests at an FM radio station I worked for.

I think the IG-5218 was a somewhat improved version of the IG-18 ... and come to think of it, I think that's the model we actually had, not the IG-18.

Someone who occasionally needs to test and repair audio equipment, or audio sections of radio or computer equipment, could use it. It is an admittedly old, but tried and true technology. I might be interested, if I had any spare cash to spend. I miss having any test equipment of my own.

From: Gerhard Baumgartner
Topic: 3113 Message: 3113

hi from austria,

i am member of this group since the end of february and i would like to build a broadband loop (50khz - 30 mhz) for my perseus sdr. i found a very interesting curcuit- and building plan here http://wl1030.com/content/ , there was a group which has build several broadband loops http://www.ng-ronde.nl/wl1030/ . those who are interested in this loop can download the general info of this loop here, it´s the file "WL1030": http://www.4shared.com/account/dir/6459794/8254f480/sharing.html?rnd=0

does anyone of you already has built such a loop or heard something about it´s usefulness in practice? any comment is welcome!

thx

3116. Of Gutters and Overhead Wires

Yahoo group: SkyWires
Date: 2008-07-07 14:52:52 UTC
From: Keith
Topic: 3116 Message: 3116

I need an NVIS-type antenna for 80 & 40 Meters and am considering a full wave 80 meter loop. My property will just barely allow it. However, it will be at most 11 feet off the ground and 1-1/4 of the legs will be hanging from rain gutters. One other leg will be under power lines, way under.

Question: Will the rain gutters, power lines, or the low antenna height make this a fair antenna or just a poor dummy load and waste of copper?

Yes and no. Depends a bit on who you want to talk to. Low eg 15 ft or less, resonant antennas 1/2 wave dipoles or 1 wave length loops, at frequencies in the 80-40 m. range work very well at distances up to 100 miles. The reason I say 100 miles is that that is my experience with Northern Trappers radio communications. Often trappers will have 3 watt SSB radios in 5 mhz range which they use to communicate back to their villages. I have seen them work very well at a distance of 40 miles using a dipole with center up 10 ft on a pole and the ends only 4 ft off the ground. I suppose that is about as NVIS as you can get.

Certainly keeping as much of it away from power absorbing objects as possible/practical would be in order. If you are looking to make contact with stations beyond that 100 miles your antenna will in effect become a dummy load.

Hi Mike. I might be able to shed a little light on the subject. I am a moderator for a group called dxer. I have had the group for some seven years. Within the past week or too I can send messages log into my group but nothing is being posted. For one thing it is very difficult to get ahold of yahoo by any phone number. There email is more of a one sided converstation. Anotherwords you cannot tell them about any problems. If any one knows how to get someone at yahoo a little attention it might help every ones problems. So don't blame the moderator he can't do much about it. Balme yahoo. I have been trying for two weeks with no luck. The only thing I hear from them is each time I post they send me an error code and that they have given up trying to fix the problem. hope this helps. 73's mike kc9ldo

Yes, there are intelligent antenna discussions here ... lots of them.

Just use your delete key on the spam messages. Unfortunately, that's all the moderators can do too; they don't have privileges (in this group) to prevent spammers from joining, so this group will not be spam-free.

If your email program allows filtering incoming emails, searching for "freebies" will catch about 75% of the recent spam.

There's at least two other loop antenna Yahoogroups. Feel free to join them too.

Me, I don't see very much spam on this group. I am subscribed through Gmail, which filters out 95+% of the spam (controllable by me), and what gets through, is either caught by my own filter, or easily zapped using my keyboard's Delete key.

Looking back a few weeks, I see discussions about baluns, insulators, 6 meter and 160 meter loops, wire gauge, trimming loops, etc. Stay tuned, and it will come.

Unfortunately, getting a hold of someone at Yahoo won't help (for this group).

The problem is the "owner" of the group is gone, and he didn't leave the "moderators" with enough control to prevent spammers from joining. Yahoo's policy is, and has always been, that the owner has supreme control over their group and even they (Yahoo) will never, ever, intervene. Even if the owner dies, Yahoo will not appoint someone else the new owner, or increase the moderators' privileges, no matter how hard you plead and beg.

Like it or not, it's Yahoo's policy. You may say it is stupid, but the other side of the argument is it prevents some dude from hijacking a group against the owner's wishes. Yahoo sides with the owner, which (I think) is the only thing that makes sense; he is after all the one who owns the group.

Any good group must have multiple moderators with FULL privileges.

Andy

Once again, we have had more complaints about and comments on the presence of spam messages on this reflector than we have had actual spam.

Delete it. Post something about a new variation of a skywire loop or something instead.

Mine's still working well, thank you. That despite my neighbor hiring some guys to take down some trees who managed to take down one leg of mine. Of course, one support may have strayed over onto his property just a tad!

From: Jim Dunstan
Topic: 3131 Message: 3147

I don't know if this is off topic (since I am not giving away (fr----bies).... but I have a question or topic of discussion ... concerning radiation pattern of a horizontal loop. I have heard a number of people talking about the 'best' place to insert the feed-point. Now I can understand that there are physical considerations ... e.g. the orientation of the supports vis-a-vis the operating shack, and placing the feed point near a support in order to carry the weight of the feed-line etc.

Leaving physical considerations aside, it seems to me that if the loop was perfectly symetrical e.g. circular in shape it would make no difference at which point the feed line was inserted .... unless the feed line has some influence. Most horizontal loops are supported by at least 3 supports (triangular) or 4 (rectangular). Does the feed point have any significant influence on the radiation pattern as a result.

Jim,

There is indeed a difference in the radiation patterns of a (square/rectangular) horizontal loop when from a corner vs (the middle of a) side. This is modeled by the late Mr. Cebik W4RNL, and can be viewed on his website at:

http://www.cebik.com/radio.html

I see that the person maintaining the site now requires a login and password, but you'll find several very good papers there on the horizontal loop antenna.

Regarding your hypothesis on the symmetrical radiation pattern of a circular loop, I suspect that you might be correct if the loop was high enough (e.g., 1.0 wavelengths high or greater). But, I suspect that when the loop is much lower that 1.0 wavelengths, that the feed pattern is affected by the feedline and the relationship of the antenna to ground. Many horizontal loops are used in the lower bands, especially for NVIS type work (80M & 160M bands especially) which are only 30-40 feet high. In these circumstances, the loop is only 0.1 or so wavelengths high (80M), and I suspect that the radiation pattern will not be symmetrical in a true circular loop.

Note that Mr. Cebik also modeled antennas for NVIS, and determined that the optimal antenna height for working NVIS was (as I remember) ~0.15 wavelengths high.

I do not have a login to Mr. Cebik's website (yet), so this is all from memory. I hope that I haven't made a mistake.

Hi Bill,

Interesting ... I'll have to check out some of Mr. Cebik's research on the horizontal loop. I assume the 'deformation' of the radiation pattern provides some directional properties. I know I have quite a few of his articles in .PDF format. I know that .15 wavelength for NVIS is pretty much on .... In my earlier years in the north country ... (still within the tree line) ... Native trappers used SSB radios in the 5 mhz range for communications back from their camps to the village.... usually 40 to 90

miles apart. They would string dipoles up in the trees about 15 to 20 ft high and had no problems with reliable communications using 2 to 3 watts output. Not being aware of NVIS for short communications I thought and suggested hanging the antennas higher up would be better. Being very polite, they would tell me the low antennas worked just fine hi hi .

I have seen portable stations set up with the antenna only 10 - 15 ft high which proved reliable at short distances ... and in the Arctic I have even seen HF antennas set up using ski poles !! At a distance of a few hundred miles the frequencies would be silent.

In addition I assume NVIS is only useable with relatively low HF frequencies .... perhaps up to 40M. Beyond 40M I would assume NVIS would account for almost zero propogation. The 5 mhz range seems to be the magic frequency for reliable NVIS communications.

3150. Horizontal Half Wave Open Loop in the attic

Yahoo group: SkyWires
Date: 2008-08-02 01:57:16 UTC
From: Jonathan Helis KB5IAV
Topic: 3150 Message: 3150

For the last several months, I've been experimenting with a horizontal half wave open loop in the attic of my 1 story house. It's basically a dipole in the shape of a horizontal loop 25ft x 5ft, for a total of 60 feet of wire. It's fed with 300ohm TV Twinlead, a 4:1 balun, and it's tuned with an LDG Z-11 Pro autotuner.

I've been working alot of PSK31 not running more than 40 watts and here are the results I'm getting:

On 20 meters, I've been able to work Alabama, Floriday, Georgia, Kansas, Kentucky, Michigan, Missouri, New Mexico, New York, Ohio, Pennsylvania, Tennessee, Texas, and Wisconsin. On the DX front, I've worked Guatemala, Cuba, Costa Rica, and Puerto Rico from my Louisiana QTH.

On 40, I've worked Florida, Indiana, Kentucky, and Oklahoma.

With some of those close in QSOs on 20, I wonder if my antenna is a cloud warmer.

I've tried loading on 17, 15, 12, and 10 and haven't made any PSK31 contacts.

I was wondering how that performance compares to what others are getting right now. I'm thinking of replacing the antenna once summer is over and I can get into the attic, possibly with an OCF dipole or something like that.

Any comments are welcome.

This is a link to a NEW FREEBIE PAGE for this week so I thought I would,
share it with the group...enjoy!

The link goes to the latest freebie page where you can collect TONS of
items for FREE! There is so much on offer that its definately worth the visit.

http://www.freebiet elegraph. com/?page= 13

When you have had your freebies, be nice to your family and friends and
pass on the link above, like I did!

Take care and have a great week!

FYI, this particular spammer ("christiedurning") joined this group on August 18 ... today.

That's how they work. They sign up and send spam, then either quit the group or let themselves be dropped before signing up again with a different name.

As you know if you've read any of the discussions about spam on this group, the moderators are powerless to *prevent* spammers from signing up here. They can only ban them after they've done their stuff.

Do what I do ... just ignore them. It only raises your blood pressure if you let them get to you! I get lots of unwanted mail in my postal (snail) mailbox too, but there's not much I can do about it.

I see you read the Digests so you can't just delete them or use a Rule to auto-delete them.

Andy

3169. Help With Building A Loop

Yahoo group: SkyWires
Date: 2008-08-28 14:54:32 UTC
From: wargodjd
Topic: 3169 Message: 3169

Putting up a big loop, probably bigger than 160m. This will be my first antenna effort and I could use some advice.

How to de-ice? Up here in Maine a big loop will ice up heavily I should think. Other than transmitting, how to get the loop to melt the ice? Just switching in 115 volts AC seems dangerous.

Going to use homebrew ladder line. Does this mean a 4:1 current balun inside the shack is best? Can I homebrew one that is as good or better than store bought? My rig is a Kenwood 940 with an ATU. Definitely not a balanced line tuner.

Lightning is a worry, should there be a switch outside the shack? Just unscrewing the coax at the ATU seems really risky.

Thanks for the help.

Greetings,
For Ice and wind take a lesson from your local power
company. Buld it heavy and strong.
Use a dark colored wire if you can as it will absorb
heat and melt the ice.
You should have a Balun inside your tuner. Use it.
Make a Lightning arestor OUTSIDE you shack.
Use a good ground. I have made one from a 4 X 6 inch
3/8 hunk of copper and brazed two spark plugs into it.
I grounded the copper plate and hooked the lader line
to the spark plug tips. It was just some stuff I had
in my garage. Keep your tuner grounded to the same
outside ground as your spark gap.
Best to have ONLY One ground for everything.
And use Heavy copper wire.

Best of luck.

I have no experience with de-icing a loop antenna .... however a controlled DC current via the ladder line might be a useful. A variable voltage DC supply might work ... starting at the lowest voltage work up while monitoring the current to see that it stays within the limits of the supply. Your ladder line should be of the same gauge or larger than the antenna wire and be certain all connections are well done. I have used this technique de-icing copper piping.

>Going to use homebrew ladder line. Does this mean a 4:1 current
>balun inside the shack is best? Can I homebrew one that is as good
>or better than store bought? My rig is a Kenwood 940 with an ATU.
>Definitely not a balanced line tuner.

There is almost no way to predict what the impedance is going to be at any particular frequency at the end of the feed line where it joins your tuner. A current balun .... in fact even a voltage balun or transformer does not work well at high impedance values. They are primarily designed and work well at around 50 ohms. As the impedance gets hi they become less efficient and absorb power and become outright dangerous if you are running high power. The ideal is to use a tuner designed for balanced feed line .... or you can feed the balanced line directly to the unbalanced output of your present tuner and then isolate the frame from ground and feed to your xcvr via a 1:1 current balun.

>Lightning is a worry, should there be a switch outside the shack?
>Just unscrewing the coax at the ATU seems really risky.

Yes, there should be a direct path to ground outside the shack at the point where it comes into the shack. The connection can be via a short gap to the ground wire. I would also recommend un-plugging the line to the tuner inside the shack during storms and shorting the input to the radio. Not sure what your wx in Maine is like, but large wire antennas in some locations can build up high static voltages .... the small gap between the feed line and the direct ground connection can serve the second function of providing a route for these voltages. I have seen wires shorter than what u describe drawing sparks to ground in well in excess of 3 inches.

That's a heck of a project! Should be fun!

I spent the first 24 years of my life in Central and Eastern Maine and don't think I would worry too much about melting ice. While I live in Western Washington now, I use Coperweld copper clad steel wire for even my short dipoles and would certainly do the same for a big loop. It comes with a sturdy black insulation as well. It's not as cheap as 14 gauge stranded THHN from Home Depot, but it will lessen the chance that you'll spend more time splicing breaks than operating.

The corner supports would concern me more. A nice gentle bend as opposed to something sharp is preferred. Sharp bends become cantilevered points which will fail prematurely even without ice. With the possibility of ice, it becomes even more important.

dear groupmembers
i made a fullsizeloop for topband about 168m .... didn?t really measure just made it 170m long and then cut and try, cut and try .....
it is now about 168m long and it is made of aluminium fence wire (lightweight but strong)
i feed it with a ladderline for 80m with about 18m of ladderline and for topband i switch in another 20m so i feed it with a quarterwave lenght of line
the impedance on these bands are low at the feedingpoint and after the ladderline (in the shack) the impedance is 400 - 500 ohms
i made a homebrew 1:9 balun (not an unun!) with an amidon red 200A and it works great on ANY band with it ...
on 40m it is fed with long or short ladderline and the resonance is for the short line abt. 7.05 and for the longer line abt 7.15
on the higher bands there are many resonance points so you can use it anywhere you want ...
to manage all the measurements i made an excelsheet for all my notes....(see atached file!)
the impedance on the lowbands are low but will be transformed high via the laddelinelenght of a quarterwave
on 40 you have abt 400 ohms and a halfwave or fullwave feedingline so no transforming
i spent abt. 2 days with cut and try for this antenna but now it works superb for me....
the extra lenght is under the roof of my house and i have to switch it in between for the topband or if i want to use the upper part of 40m
the feedingline is a so called windowline of 450 ohms but surely you can use a homebrewed one if you couldn?t buy it somewhere
if somebody wants the desciption of the balun just ask and i will explain it
good luck with building such a superallbandwireantenna :-)

3176. first loop entry suggestions

Yahoo group: SkyWires
Date: 2008-09-01 11:37:04 UTC
From: n1dve
Topic: 3176 Message: 3176

I searched around the old messages and didn't come up with much so here we go... I want to put up my first loop and need entry suggestions for my ladder line into the shach. I have a large metal conduit for coax entry so I cannot use that as far as I know. I have storm windows so I need to stay away fronm the metal frame I believe but not sure how far. Thinking about maybe drilling through the wall and using two 1 foot pieces of RG8 as a feedthrough with the ladder line on both sides and tying the shields together without grounding. Then a knife switch to open the feedline and ground when weather gets scary. The ladderline will then go to my Dentron tuner then to the rig. So I am not sure how to go, maybe a wood panel in the window with the laderline popped through without a feedthrough? I kinda like the coax feedthrough idea if it would work OK but I have to tink about drilling through the side of the house. Can I use the feedthrough idea but just let it lay between the metal storm window frames? Consider I would like to use my 1200 watts as well and give me your suggestions or just tell me what you have done so I can consider other alternatives. Thankd in advance for the help! 73, Jacqui

To feed ladder line through a window try placing
a couple of 3/8 inch PVC pipes drilled and spaced
into the frame below the window.
This will give you a nice looking feed through that
can be patched latter on if you don't want it.
The PVC pipe will insulate for you .

Hi,

You Have a lot of good suggestions yourself. Perhaps you could join two of them together to avoid drilling additional holes in the wall. You mention a large metal conduit for coax. If it is large enough for 2 additional runs of RG8 coax you could run a pair taped together of the necessary length to go from the ladder line on the outside right to the antenna tuner at the operating position .... or to the switch ... etc ... your choice. I am sure adding a piece of coax balanced line will have little if any effect on your antenna operation. If you tie the shield together further spacing is not necessary ... if that was the reason you wanted to drill holes in the wall.

Jacqui, as mentioned by someone else, you can simply use two pieces of coax run parallel through your current coax feedthrough conduit. Use each of the center conductors hooked to each of the two conductors of the ladder line, then tie the shields together and ground them...some say on both ends, some say on the outside end, but I just ground the rig/tuner end of the shields to my main station ground and it works fine.

If you can switch back to ladder line okay on the inside of the house to the tuner without getting within a few inches of anything metal, go for it. My twin run of coax did run all the way to the tuner, which had a 4:1 balun on the output for balanced line. Now I've gone to a high-power auto-tuner with no balun and I'm using a 1:1 balun inside the shack and a short run of coax to an unbalanced tuner output.

Good luck with the loop. She's a fine antenna. I've got some stuff about loops and ladder line on my web site at www.n4kc.com if you are interested.

OK everyone, thanks for the help! I think I will go with the 2 short RG-8 runs through the wall but it got me thinking. Everywhere I see that I should not get the ladder-line near metal but here I am surrounding each wire with a shield that is grounded. I know everyone does it so it must work. I'm curious, why is this not count as a metal object, especially since it is at a ground potential? Can anyone help me digest this? Why wouldn't two wires unshielded be better? Ya gotta love this hobby, it constantly makes you think! Jacqui

3183. increasing size of horizontal loop from 80 to 160 meters

Yahoo group: SkyWires
Date: 2008-09-05 16:05:39 UTC
From: Alan Wilson
Topic: 3183 Message: 3183

Hi all, I just finished almost doubling the wire of my 75 meter horizontal loop. One end has square corners while on the end one end is square while the other corner extends to the property line. The antenna is fed with 450 ladderline, runs to the shack wall and is connected inside via a 4 to 1 balun. 160 will tune fine with the internal tuner as do most bands with the exception of 75 meters which can be tuned in fine with an external tuner. Height varies from 60 feet on one corner to about 40 on the others. I expect to have a little better dx angle on 75 while 160 will be NVIS. I don't know about the other bands, they do load up easily. Has anyone built or modeled this variation of the loop antenna? I'd like to hear some experiences or see a model if someone can do this...thanks es 73, Alan Wilson

Hi,

Okay, here is my take on the subject from my experience and what I have read over the years. Balanced feed line has 2 favorable characteristics that make it very desirable for Amateur antenna work: first, it has low loss .... especially in situations with high SWR, and second, as long as you keep it 'balanced' there is little RF radiation from the line. Keeping it balanced is the key .... e.g. the RF voltage and current curves are equal and opposite on each side of the line .... which allows cancellation of the RF fields.

Now, in a situation where the feed line comes close to metal objects it is imperative that the line should be 'dressed' in such a manner that a sufficient distance is kept between the line and the metal object .... eg more than the distance of the small field surrounding the feed line .... and any interaction that does take place should be equal to each side of the line.

First, the distance ... eg how large is the field around the line? Well the extent of the field around the line is proportional to the distance separating the two wires that make up the feed line. Conversely, the efficiency of the line is the opposite ... eg the wider the separation the more efficient (eg line loss ... especially due to SWR) the line. Generally speaking the greater the separation of the wires in the feed line the higher the impedance of the line, the lower the loss, and the larger the radiation field around the line. As a consequence line with wide separation is more susceptible to interaction with surrounding metal objects and more care must be taken in 'dressing' the line between the antenna and radio. Someone posted pictures of a home brew feed line system with wide .... eg 4" to 6" separation and dressed it close to objects like rain gutters etc ... which is not good practice with such wide spaced line.

Now narrowly spaced feed line like 300 ohm TV twin lead is much more immune to surrounding metal objects .... even though it has higher loss ... since the radiation field is very small due to the close spacing. At one time

they used to manufacture 75 ohm balanced line ... which even more immune to metal objects ... in fact you could almost treat it the same as coax. In my experience TV twin lead can be coiled (loosely) with almost zero change (as indicated on an RF bridge).

How to maintain balance given what you got ? Some rules for dressing balanced feed line: - keep it a sufficient distance from metal objects .... the sufficiency depends upon how wide the field is around the line ... which in turn is related to how wide the wires are separated in the line. 6" is sufficient for 300 ohm twinlead ... and goes up with wider spaced line. If the line is running parallel to the metal object ... eg like down a metal tower ...keep it as far away from the towr as practical and put slow twists in the feed line to aid maintaining balance. If crossing the metal object at a 90 degree angle ... there is little interaction as each side is affected equally ... eg going past a rain gutter.

The coax theory is as follows: The center conductors of each of the 2 pieces of coax become the balanced feed line. The 2 pieces are dressed next to each other ... best to actually tape them together along their length and treat them as a single cable. The shields are connected together .... usually at one end .... which in turn may be connected to a short run to ground .... (in my experience not essential). This arrangement seems to be immune to close metal objects, is flexible, and electrically insulated. Remember, the key is to keep them together as one as this insures minimal surrounding RF field due to maximum cancellation. As soon as you separate them you introduce a surrounding field and you are back to where you started.

When you bring them through the wall ... make sure they come through the same hole as one. This balanced feed line introduces additional loss (over the open wire line) that is of little consequence as it is just a short length. However, it maintains balance with a minimal external radiation field as it is totally cancelled with the shields soldered to each other and placed next to each other along their length.

> does it so it must work.

I would not say everyone does it. From what I've read, many ladderline users are very hesitant about doing that.

> I'm curious, why is this not count as a
> metal object, especially since it is at a ground potential? Can
> anyone help me digest this?

The main reason to keep ladderline away from metal is it tends to unbalance it.

Also, for another reason, and that's that ladderline is somewhat high impedance. There is greater ability to couple stray signals from that metal into the ladderline, or vice-versa, than would happen at 50 ohms. Also, the presence of the metal (over some length) lowers the ladderline's impedance.

In my judgment, if you are working HF, a foot or two of dual coax is not so bad. The discontinuity it causes to the impedance is electrically short compared to a wavelength, so not to worry about that. Try to keep everything symmetrical going into and out of the coax.

By the way, you would be well advised NOT to rely on a knife switch (or a manual reconnection) to protect your gear and your house in a thunderstorm. You should also have something permanently attached. You don't want your house to burn down if you forget.

Andy

At 11:59 AM 9/7/2008 -0700, you wrote:

>Do I have to use ladderline for a Skywire or can I use 50 ohm coax?
You can do both.

If you use 50 ohm coax then the feed point of your antenna must be 50 ohms as well (only a slight mismatch is acceptable). This means the antenna must be resonant at some particular frequency within a particular band. If you want to operate on more than one band then you will either have to put an automatic coupler at the feed point (to deal with the mismatch) or use ladderline with a tuner.

So, if you build a skywire to 80m dimensions and feed it with coax then it will for all practical purposes be a monoband antenna on 80m. If you use the same 80m skywire with either a coupler and coax or ladder line and tuner then you will be able to operate effectively on all bands 80m-10m.

From: James Townley
Topic: 3186 Message: 3189

If you plan to use the loop for just one band, a 4:1 balun at the feed point would work just fine. For multi-band usage, the ladder-line would be the best choice. As a multi-band antenna, the higher swr on other bands would convert itself to heat in both your coax and your balun. I use 300 ohm twin-lead to feed my antenna, and a link coupled tuner (Johnson Match Box) as an antenna tuner. I once used a coax 4:1 balun arrangement, but on bands where the SWR was a little higher, the balun would heat up and cause my swr to rise considerably during lengthy conversations, and in extreme cases of higher impedance mismatch, it would happen during tune up. If you use a full wave loop for any given frequency, and don't plan on using it on other bands, then it should work out fine.

It has been widely accepted that using a link-coupled tuner, with balanced feed-line is the most efficient way to transfer power from the transmitter to the antenna. I haven't tried using the balun near the house with a short run of coax into the shack. If you use this arrangement, I would use a heavy-duty balun rated for 4k watts or more. Especially if you plan to run more than 500 watts.

Have fun,
Jim WØHRF

Hello SkyWire Group,

I'm new here.

I've been running a skinny loop....100 feet by 24 feet for about a year
with good results on 80 through 10 meters using a tuner and a 1:1 current
balun from DX Engineering. A 4:1 current balun does not work well with
my ATR-30 tuner and loop, fed with 450 ohm ladder line.

See my loop and system diagram at:

http://ph.groups.yahoo.com/group/SkyWires/photos/view/3cb8?b=1

Tom, I don't know which is most impressive, your antenna or your nicely done diagrams!

I keep hearing various discussion about using 4:1 or 1:1 baluns to make the transition ("transformation," if you will) from balanced to unbalanced to the tuner. The argument that makes most sense to me is that any multiband antenna such as the loop will present myriad impedances across the HF spectrum and it is best to pass along to the tuner pretty much what the feedpoint presents...using a 1:1 current balun rated much higher than the power you will run into it.

The larger matching problem will be very, very low impedances in the vicinity of a few ohms, and if you are stepping down at a ratio of 4:1, that is especially problematic. I'm not surprised the 1:1 works better, and the DX Engineering baluns are superb.

dear antennabuilders :-)
i feed my 168m loop with a 1:9 balun ....
the reason is:
i feed it via a quarterwave lenght of ladderline on the 2 lowest bands
on topband 38m on 80m abt. 18m ....
the low impedance on the feeding point is transformed via the ladderline to
about 400-500 ohms so the balunn will do a fine job
on the higher bands the feeding point impedance is higher (300 - 500 ohms)
and the ladderline is not transforming because it is almost a
matched situation and a halfwave or fullwave lenght....
160m 80m 40m 20m 17m no tuner needed
15m 12m 10m swr is about 1:1.5 - 1:2 ... so the internal tuner will work
fine
or you can use the pi section of your pa tu tune ...
i think my solution is the best way for going multiband
i can upload the excelsheet i made for my notes
the only thing i have to do is i have to swich in or out the extra lenght of
ladderline of abt. 20m
but the losses will be lower when tuning the antenna with the line instead
tuning it with a tuner
made some test with the shorter lenght and tuner and with the longer run
without tuner
10db difference !!!
maybe it is a nice idea for somebody else

Hi,

That is an interesting ... but not a new way of ' tuning' the antenna system .... that is of adding and subtracting lengths of balanced feed line in order to match the system to the transceiver. I used a similar system years ago when end feeding a horizontal wire (Zepp). The Zepp is a half wave length at the lowest band and presents a high impedance at the starting band and its harmonics ... eg 80,40,20,10m. This high impedance is transformed to a low impedance near 50 ohms by 1/4 wavelengths of feed line. I used ladder line for the first length and then pieces of 300 ohm line for impedance transformation at the other bands.

Just as a note, I found that laying 300 ohm line straight or in loose coils caused little difference in performance.

If I was designing the system for maximum efficiency I would eliminate that RF transformer .... an obvious weak link. I would choose lengths that transform the impedance at the frequencies/bands of choice directly to 50

ohms and then connect the coax directly to the balanced feed line. All you need is an RF choke at this connection point to maintain feed line balance ... eg remove antenna current from the coax shield. Then feed the coax directly to the transceiver or to a standard unbalanced tuner (which is maximally efficient at this impedance range) in order to 'tweak' the match for best operating conditions for your radio.

Now to be fair, the comparison you made between feed systems .... which produced a 10db difference in radiation .... is really a comment on the efficiency of the particular antenna tuner you were using and the particular band/frequency of the test. I will hazard an opinion that if you use a well constructed tuner designed for balanced feed lines, feeding quality balanced feed line between the tuner and the antenna .... with no intervening RF transformers or baluns .... that comparable measurements at randomly selected frequencies across the bands would seldom ... if ever demonstrate a full 10db difference.

To obtain a 10db difference the feed system would have to absorb almost 90% of the power .... which would make me guess you ran the test using QRP .... or your tuner would go up in smoke hi hi.

My suggestion for efficient all band operation at all frequencies would be as follows:

1. Use a well designed balanced tuner with quality components.
2. Feed the antenna directly from the tuner with quality balanced feed line
3. Eliminate all RF transformers or baluns between the antenna and the tuner.
4. Modify the balanced feed line .... eg by adding/subtracting lengths of line only on those bands/frequencies that present difficulties.

dear jim
you are right
it is not the best to use a balun cause its losses BUT
i could not find a solution better than used now
i wanted an allband antenna with good performance
the abt 10db losses i recognized on topband with the short feeding line
this is caused by the tuner (differencial highpass t) and the mismatch the
balun has to handle when not using the longer feedline on topband
and i am sure with a high perfonance ballanced tuner the losses will be
lower
but i had to use what i have ... an unbalanced tuner with a balun for
ladderlinefeeding
i recognized that the swr was low with some more or less lenght of
feedingline and just tried what will happen when changing
the 1:4 balun to a 1:9 balun ....i wrote before that it was SUPERB to use
this antennasystem on many bands with
the tuner switched OFF!!! if you don?t need the tuning parts in the tuner
only the balun then the losses will be lower than with the tuning parts
switched in
(no coil=no coil losses)
i could not find a point on my different lenght of feeding line where the
impedance is almost 50 ohms if i could i would have used a 1:1 balun (rf
choke)
i spent 3-4 days with different lenght of feedingline (had some shorter
parts from a fieldday) and made notes in an exelsheet
i will upload it in the filearea
happy dx?ing

Hi,

No doubt, the tuner with balun is the culprit .... if the particular
frequency presents a high impedance to the tuner arrangement the balun will
absorb lots of power ... if you keep the power low it will work without
destroying itself hi hi.

As they say, there are many ways to skin a cat ... and your system works
for you ... as an aside, if you can get the end of a particular piece of
feed line to measure 200 ohms then a 4:1 balun works vy well. I have used
this with resonant folded dipoles made of and fed with 300 ohm line. They
present a good load to a 4:1 balun. I have fed such antennas with up to
350 watts with AM modulation using TV twin lead .... with good
efficiency. Making do with what you got .... when you understand what you

are doing is great fun and satisfaction when your plans work hi hi

73 and gud dx

3203. Re: increasing size of horizontal loop from 80 to 160 meters

Yahoo group: SkyWires
Date: 2008-09-18 19:33:53 UTC
From: Mark Brown
Topic: 3183 Message: 3203

Alan, I've been operating a Horizontal Loop similar to your config for some weeks now and will share my experiences. I paced off the yard and a FW loop on 160m was a tight fit. Several hams mentioned I might get away with less wire by using insulated (lower VF) so off to Home Depot for a 500' spool and some PVC elbows for 5 supports in trees.

The 500' sagged too much and since I couldn't make the trees move I took 53' out of the span to make it 447'. It's fed with 60' of ladderline about 10 feet from the SE corner for convenience. The overall shape is closest to a parallelogram.(see http://en.wikipedia.org/wiki/Parallelogram feedpoint is near "D", "E" points northeast.

It tunes all bands but there's a catch. My Heathkit SA-2040 will tune it from 80 thru 6, but the Murch tuner will tune 160 thru 10. Both are T-Match, so it's probably an issue of stray iductance/capacitance of different tuners.

Operationally, it's a nice cloud burner on 160 thru 40 with very good reception nighttime reports on 40 using 100w. On 20 & 17, this thing sings. Europe is booming in and the background noise level is way below my OCF dipole. Actually the receive noise level on all bands is lower than the OCF. No openings to speak of on 15/10 so nothing to report.

I have not done any modelling on this but the results are very encouraging. This winter when the leaves are off the trees, I'll shoot a few more lines in the higher branches to get the height AGL from 50' to 70'.

73,
Mark

Mark, thanks for the info. I'm pleased so far with it. I've yet to try 160 though and of course I'd like to get it higher. I wish I could find someone to model it for me, I'd really like to look at the results...73, Alan

3210. Loop wire TOUCHING stuff - what happens?

Yahoo group: SkyWires
Date: 2008-10-02 14:34:26 UTC
From: Benson
Topic: 3210 Message: 3210

I live on a small city lot: 130 ft by 60 ft. Good sized house at the front, separate garage apartment building in the back. No trees on the corners of the lot to make a nice tidy square loop the proper way with support ropes, insulators, etc.

I was wondering if this would work: Using an SGC coupler on outside of my house, running (insulated) 14ga or 18ga antenna wire around the apartment building itself, over the roof of the house (touching the roof in places), around a tree, then back to the SGC. I would have the antenna fastened directly to the SGC and coax running from the coupler back to the radio. My power output is limited to 100W max.

The more basic question is: how well do skywires work when in contact with wood and other non-metallic material? I am hoping to have something that will tune up on 160 before the sunspots start coming back in force.

73,
Benson

Hi Benson - same here also, my loop is made of no.16 insulated household wire and it goes up from the sg230 tuner mounted on windows via tree limbs in a square shape on the flat top and comes down to the tuner earth end. So far it has performed superbly, the total length of the wire is around 130 feet and I haven't found any bad effects coz of tree limbs.

Good luck vu3mes india

You fellows are certainly free to do as you wish. I subscribe to
both groups but see little activity on the newer one.

By the way, there is a little button, usually near the top of your
email reader, that either says, "Delete" on it or is marked with a
big, red X. With any email that is obviously spam, all you have to
do is click that button once and it goes away forever. I've gotten
pretty good at it. It takes less than a second and only a slight
movement of my right hand on the mouse.

Just an estimate, but I bet most of you could have deleted a hundred
of those "free stuff" and "I want to meet you" postings with the same
time and effort it took to tell us you were leaving this group.

3229. RE: [SkyWires] 80 Meter Horizontal FUll Wave Loop

Yahoo group: SkyWires
Date: 2008-10-10 16:58:09 UTC
From: Scott MacKenzie
Topic: 3228 Message: 3229

I have been a fan of 80M full size loops - especially when used with a tuner on 40M...VERY effective. Very effective on 80M for relatively close (1500 miles or so) contacts. It works well on DX too - but my vertical does a bit better on really long DX (XU, JA, HL, etc. on 80M. On close contacts - out to about 1500-200 miles, the Loop beats it by a HUGE margin.

I put up an 80M full size loop for sweepstakes last year, and with only a modest effort, was able to come in first place in my section for single operator, low power (100 watts), Eastern PA section. I came in 6th overall in the Atlantic region against some really hard core contesters. I was 94th in the country. The loop was only up about 30 feet at the time. The same loop is now up at 65 feet with the peak at 75 feet. Recent comparisons have indicated several dB improvement in signal on 80M. It should be even better on 40M.

I have always used an 80M loop for FD and have been reward nicely with holding a frequency for hours at a time using only low power (100 watts).

You will enjoy it...and you can't get much simpler.

To: a un sky wires eGroup; a mod Sky Wires eGroup
Subject: [SkyWires] 80 Meter Horizontal FUll Wave Loop

Last week I put up an 80 meter horizontal full wave loop. It is 285 feet of #12 stranded and in a square shape. Each leg is 71.25 feet long and is fed in the middle of the leg that is broad side N-S. The four corners are orientated towards the NE, SE, SW, NW and is up at 35 feet in my oak trees. It is fed with 122 feet of 300 ohm window line to the Johnson Viking Match Box for 80-10 meter coverage

I did an A-B comparison between the loop and 80-10 meter fan doublet and the loop won every time on every band both close in and on DX and was also more quiet on receive. So I retired the doublet antenna.

I published a website about it at http://www.kn4lf.

3231. Question regarding Tokyo Hi-Power HC-200AT tuner

Yahoo group: SkyWires
Date: 2008-10-14 13:28:14 UTC
From: writer1stus
Topic: 3231 Message: 3231

Hi gud people!

First a brief introduction, I guess. Though licensed since 1976, I have been mostly inactive for the last 20 or so years. I am now quasi-retired and in recent months have re-discovered my passion for ham radio. I operate primarily in the CW protion of the bands and find myself now also becoming very interested in PSK. Oh, and while I do actually own a mic, I only use it on an occasional basis.

We live in southeast Georgia in a subdivision where putting up any kind of a tower is probably out of the question so I have been using coax fed monoband dipoles for 40, 30, and 20 meters. I have never experimented with any kind of a loop antenna or balanced feedline, but want to try both now; especially after perusing the last year or so's messages here. Enough with the bio, and on to my one question, though no doubt I will have several more as I try to get up a (delta?) loop in the coming few days.

I am considering purchasing a used Tokyo Hi-Power HC-200AT tuner. Will it handle balanced transmission line or must one use a 4:1 balun and a short run of coax with this tuner?

Thanks in advance!
James

>James
>N4EKZ

Hi,

The Tuner you mention is an automatic tuning unit designed to feed unbalanced line (coax) or an end fed wire antenna. In order to accommodate a balanced feed line you will have to use some kind of balun arrangement. A 4:1 balun would technically give you a range of 20 to 2000 ohms as the advertised range of the Tokyo ATU is 5 to 500 ohms. I would suggest putting the balun as close as possible to the tuner. If you find frequencies you like to operate and the tuner won't match the antenna ... then try adjusting the feed line length .... add or delete to the length on an experimental basis.

3237. Complaining to Yahoo about spam is a waste of time...

Yahoo group: SkyWires
Date: 2008-10-22 05:52:00 UTC
From: Kurt Barnhart
Topic: 3235 Message: 3237

--- In SkyWires@yahoogroups.com, "Dr.Ace" <wh2t@...> wrote:
> I got this response from abuse@yahoogroups.com after I complained
> about the Freebies spam.

I have bad news.

Once a spammer has locked onto your group address, there are few options -- they will keep spamming you again and again.

You can close the group and open a new one with a similar name (be sure to keep it UNLISTED so that the spammers don't find you). You can rename the group and most of the members will be transferred to the new group. You can also set up the group so that only members can post. Or you can make the group moderated, and set trusted individuals as "unmoderated" on a one by one basis.

When the spam arrives, then you can delete it before it posts to the group.

Don't count on Yahoo doing anything. They never did before and they especially won't now since they are laying off thousands of employees.

Good luck!

Topic: 3238 Message: 3238

> Don't count on Yahoo doing anything. They never did before and they
> especially won't now since they are laying off thousands of employees.

What Yahoo can do, and has done for me, is remove people who have actual yahoo.com email accounts and are using them to send spam.

I have had success in the past reporting some of those to Yahoo. Yahoo investigates and closes their account. Their spam actually stopped. But in the big wide world of spam, those are the small players. Most spammers these days fake their "from" address so even if it says it is "from" a yahoo.com address, it probably isn't. And then there is nothing Yahoo will do about those.

Mail that *leaves* Yahoo, from a Yahoo.com email account, is clearly covered by a TOS (terms of service) agreement.

Mail that *arrives* in a Yahoogroup, is not covered by the same TOS, and may not violate any TOS unless what they are doing is patently illegal. Advertisements in Yahoogroups aren't illegal and may not violate Yahoo's TOS, so Yahoo generally doesn't intervene when the problem is spam being received by a Yahoogroup from elsewhere. They leave that up to the Moderators of the group, to control what THEY feel is acceptable to that group. Complaining to Yahoo will not help with those.

Two of the easiest things a group Owner/Moderator can do to control spam, are:

(1) Change the settings so that membership DOES require approval.

(2) Change the settings so that messages from NEW members (and only new members) are moderated.

The Owner/Moderators of this group have chosen to do neither of these things. So it's no wonder the group gets spam, and can't do anything about it until AFTER it happens.

These two actions are easy because it requires exactly two actions per new member. Once when they sign up. A second time when they post their first message. If the first message is spam, you don't approve it, and it never reaches the group. If it isn't spam, you change their status to unmoderated. And you're done. Easy.

Until you do these things, you will forever get spam. Any Joe can sign up, post a spam message, post a hundred spams if they like, and leave, never to be seen again. Until they do it again with a totally different identity.

Even if you somehow got Yahoo on your side, they wouldn't be able to stop it until after it happens and is recognized, and by then the damage has already been done. The only way to effectively stop it, is to block it before it happens!

Andy

Betreff: [SkyWires] Half wave loop question..?

Hello evbdi...

I live in a small city lot and my antenna is for the moment an ordinary double zepp 27,5 m long and 10 m agl. It works, but it could be better so have thougt of building a vertical 40 m loop and feed it with 20 meters of 450 ohm ladderline, making it resonant on 80m and the harmonic bands...

I wonder if anyone had tried this, and if so how does it work..?
Noise..? dx...? Modelling..?

Im using a homemade z-match tuner working fb, so there will be no balun and coax stuff to mess with..:-)

Best regards de 5P1CC claus.

Hi,

I have tried a vertically oriented 40m loop supported from a 15m tower in a triangular shape with the apex at the top of the tower. I fed it at one of the lower corners with 450 ohm line to a z-match tuner. It was a good antenna but not great .... perhaps I should have tried different feed points. I have since replaced it with a 1/4 wave vertical for 40m and prefer it. The loop would tune easily on 80m and was useful for local contacts. However a simple inverted V on the same tower outperformed on 80m.

I do note in an old Antenna Handbook a short discussion on the 1/2wave loop in vertical orientation. It was square and fed in the centre of one of the vertical sides .... with the loop either fully intact or open directly opposite the feed point. I recall they indicated some directional properties. I don't have the Handbook handy .... i do remember thinking I would like to try it. The loop would be 1/8 wave to a side ... and would require 2 support points.

Yes it is.. sort of that is.. Because if i feed it with 1 half wavelength 450 ohm feeder, (in my case 21 meters or so) the system will be one electrical wavelengt on 80 mtrs. The impedance on the antennapart of the system will be high at the feeding point and the loop will be voltage fed. There will be one currentnode at the opposite point of the feedingpoint making at least one halfwave of the system radiate. Of cause ther will be loss in efficiency
because the antenna will only be 1/4 of the area of a full size loop on 80 mtrs...but it will work, and it wont be a dummyload entirely...Well yes on 160 it will be lousy..:-)

If you build a full wave loop say for 80 meters and then try to use it on 160 meters as a 1/2 wave loop you get a big dummy load in the sky as the antenna is shorted out so to speak.

Hi Thomas,

I wouldn't go that far hi hi After all a mobile whip antenna 8' long is only about 20% the size of a full size vertical and it works quite well. I would hardly call a 270 ft loop a black hole hi hi.

Jim, VE3CI

3248. Wire and Cable for Sale - Must Go due to sale of home

Yahoo group: SkyWires
Date: 2008-10-30 17:35:32 UTC
From: denisnh
Topic: 3248 Message: 3248

Hi All. Due to a series of personal setbacks, I am forced to sell my home. I am currently moving all my stuff out and am selling off as much as I can.

I have several rolls of new, unused wire. Some of it is industrial surplus, but it is all in new condition. I did NOT get this stuff free, so I'll sell it for the lowest prices I can. The price per foot is still much lower than anything surplus or otherwise you'll find anywhere. If you do find the following items for less money, please let me know. I have just posted this wire on Craig's List under the links below.

Right now I have two types of wire for sale:

1) 12 ga. PVC jacketed copper stranded, ideal for just about any type of wire antenna.
http://boston.craigslist.org/nwb/mat/893796223.html

2) Military spec RG-58/U, 50 ohm coaxial cable also in new condition, never used.
http://boston.craigslist.org/nwb/mat/897230310.html

Shipping is available for those who don't live in the area, or it can be picked up in Billerica, MA.

Thanks,
Denis

3249. [SkyWires] WTB - looking for some Lightning grounding wire

Yahoo group: SkyWires
Date: 2008-10-30 20:51:13 UTC
From: Walter Jinright
Topic: 3248 Message: 3249

Hi all,
I am looking for about 20 ft of either 8 gauge or larger copper grounding wire for grounding a 30 ft "tower" mast/antenna to a set of ground rods, nothing smaller than 8 gauge (however 2 x 20 ft of 10 gauge solid may work), but I prefer 3/4" x ~1/8" or 1" x ~ 1/8" copper strap (strip), solid preferred, but will settle for 1" x ~1/4" braided copper "ribbon".
I am grounding a converted TV antenna to a homebrew 6 meter beam, scantenna II, and a dual-band 2 meter/70 cm set of antennas on a ~ 30 - 35' mast that needs lightning protection (I am in FL). I already have the ground rods and polyphaser surge protectors on hardware, it is just hard to find the grounding wire / ribbon in my area.
Also, any suggestions on retailer would also be appreciated as well.

Thanks,
Walter kg4bvd

Re: Wire and Cable for Sale - Selling Home and it all must go.

The RG58 Coax is sold out. I'm going through my various storage locations in hope I have more and will update this thread if I do.

I have a huge roll of the 12ga and there is still some available.

Thanks to all who ordered or just had kind words of encouragement. The amateur radio community consists of the nicest folks on the planet and I'm proud to be a member.

Regarding the 8ga grounding wire, I had to run some of that from a pump motor to the breaker panel, getting my house ready for market, and found what I needed at Home Depot. But, WOW, it's expensive.

Someone had emailed me and asked for my take on setting up a horizontal loop. I sent a description of my version of setting up a skywire and it was very well received, so I'll post it in this group within the next few days. There is some stuff there that apparently isn't available anywhere else and you might say they are lessons "hard-learned" from experience. :)

Thanks,
Denis

Hello again... I had a brainwave...:-)

I made a model of this contraption for 145 mhz and it works.. ill try to describe how.. the loop itself is made of ordinary cu.wire 24.5 cm on each side which makes a half wavelength loop for 145 mhz.. i am

feeding it with 49 cm 450 ohm open line just like the hairpin in a j-poleantenna, making the electrical length equal to 1/1 wavelength. And in the shorted end of the hairpin i made a gammamatch, just like you could do with any other loop or dipole antenna, swr perfect 1:1 an as a bonus it also works on 70 cents as expected...

I tested it on two local repeaters against an j-pole made the same way, and they are accoding to reports and my own measurements very close to equal, but a bit to the favour of the j-pole which also was expected... both on 70 cents and 145 mhz... and with exactly the same setting of the gammacapacitor...

I also added two pieces of wire 25 cm long on each corner of the loop, to simulate an inverted v, and that also worked, maybe even a little better than with the loop alone.. This could be doubfull as the local beacon is so weak at my location that its hard to hear, (or measure) any small difference in signalstrength..

Hope this explanation is understandable, otherwise feel free to ask..:-)

3268. 160 meter loop Questions

Yahoo group: SkyWires
Date: 2008-12-09 23:38:37 UTC
From: Jim Snider
Topic: 3268 Message: 3268

Hi all, Jim, W8BS here. My rig is an Icom IC-703 Plus. I work QRP only so antenna is the only place I can make improvements to my signal. I installed a 160 meter loop this summer that is up 25 feet. I used #12 AWG THHN wire for the loop and am feeding it with RG-8/U. I used to have an 80 meter loop but I wanted to get back on 160. I use the tuner in the rig to tune 160, 80 and 40 on the loop.

Now, recently I installed a 160 meter Inverted L also. So far, I have been impressed with the contacts and performance of the L. I borrowed an MFJ analyzer from a friend and the L is resonant at 1.845. The best SWR I can measure on my loop is at 1.86 but 2.5 to 1. The tuner in the Icom matches the loop just fine to the rig but I'm wondering about performance of my station.

I've read a number of web sites where guys use 450 ohm ladder line to feed their loops. My questions are these:

1. Should I cut the loop back to 272 feet which will raise the distance to ground for the 80 meter loop? Raising the 160 up is not really an option.

2. Should I feed the current 160 meter loop with 450 ohm ladder line and get a 4:1 balun to put at the rig?

3. What about feeding an 80 meter loop with ladder line verse the coax?

Thanks in advance for any info and help.

3269. RE: [SkyWires] 160 meter loop Questions

Yahoo group: SkyWires
Date: 2008-12-09 23:51:10 UTC
From: Scott MacKenzie
Topic: 3268 Message: 3269

Regarding the 80M loop. I feed the 80M loop with a random length of 450 ohm ladder line because I use the loop on multiple bands - it works extremely well on 40M....If I was only going to use the loop on 80M, I would feed it with coax and a 75 ohm matching section.

From: Jim Snider
Topic: 3268 Message: 3270

How high up is your loop?

Also, mine is in a rectangle shape but almost a square.

Hi Jim,

This is another Jim hi .... a lot of questions ... but first .... you are running QRP and as you mentioned the antenna is important ... especially efficiency .... that is you want as much of your power up in the antenna as possible and not warming up the feed line. Start with first principles

.... If you design your loop to be resonant at a particular frequency/band and you feed the loop with coax .... then for all practical purposes that is the only band for which the system is useable! This is because the loop will present a reasonable match to the 50 ohm coax at the fundamental frequency only.

If you have a 160M (1 wavelength) loop fed with RG8 it will be a good antenna for 160M and useless on 80, 40, or other bands .... especially with QRP. You will no doubt be able to match the end of the coax (in the shack) to the rig .... but the amount of RF that actually gets into the antenna will be negligible as almost all the power will be consumed in the coax feed line. Coax feed line is notorious as an RF 'sink' when dealing with high SWR.

If you want the loop to be multi-band then you must deal with high SWR loss by using ladder line .... or use an automatic antenna coupler (like an SGC) right at the feed point of the antenna.

Jim, VE3CI

dear jim
see in the files section
http://f1.grp.yahoofs.com/v1/AHc_SdhhIgVggM7AbroX_bTlKX7WlN7ppR5esCmgr9NAwukShZ4TIKfAlH5T1SKWhN92bA4YDAXBOZHjob5i4YNqkZb0/loop.xls
i use a 168m loop with ladderline with superb results
fed vial 2 different lenght of ladderline and a homebrewed 1:9 balun
if you look in the excelfile you see my notes
i can feed this antenna an many bands without a tuner and on the other bands swr is quite low ... so the losses are very low in the tuner
maybe this is a little help for you
best 73´s de dg9bfc
ps any questions?? just drop me a mail

OK. I think I'll get some 450 ladder line and replace my feeder. Now, for balun, will the LDG 4:1 (voltage) be a good one to use, or should I use the MFJ-911 4:1 (current)?

From: Siegfried Jackstien
Topic: 3268 Message: 3275

dear jim
on my antenna i use a 1:9 balun (homemade) .... but i do use resonant lenght of feedingline
it is quarterwvae on 80 or quarterwave on 160 ....
i use it that way cause with this configuration i don´t need a tuner on most bands
just see loop.xls in the filearea ....
but if you can not use it that way a 1:4 with random lenght would work for you
surely you have to use a tuner on every band when you go that way ...
best were to use a balanced tuner with the balun on the input side
cause baluns don´t like to transform reactance very much
hope that helps a bit
most important is to change the feedingline to ladderline cause it has lower losses
the rest will be experimental
on my loop it took me 4 days with cut and try cut and try cut and try ....
that´s why i made the excelfile for my notes :-)

3277. Urgent News: John "Fred" Clement (W2FC)

Yahoo group: SkyWires
Date: 2008-12-12 01:25:44 UTC
From: geratol925
Topic: 3277 Message: 3277

This is John "Fred" Clement's (W2FC) daughter.

I need to relay some unfortunate news. You may have known that Dad was not feeling well over the past two months. It is with deep regret that on Wednesday, 12/10/08, my father passed away from lung cancer. We all feel it necessary to pass on the information since speaking with you whether it be on the internet or over the air was some of his most cherished moments.

The service information and home address is listed below for anyone who is local to the area or would like to send a quick note.

Details for John F. Clement W2FC:

Home Address: 1141 Hyman Ave. Bay Shore, NY 11706

Viewing: Friday, December 12 @ Chapey's Funeral Home in West Islip, NY from 2 - 4:30pm and 7 - 9:30pm

Funeral Services: Saturday, December 13 @ St. Patricks Cathedral in Bay Shore, NY at 10:00am.

***** MERRY CHIRSTMAS ****

HMY2K8 - A multiband HF (Homebrew) transceiver :

for more information visit :

http://vu2sgw.blogspot.com/2008/11/hmy2k8-multiband-hf-transceiver.html

TECHNICAL SPECIFICATIONS :
Frequency coverage: Ham Bands
3.500 - 3.600 M.Hz (80 M)
7.000 - 7.100M.Hz (40 M)
14.000 – 14.350 M.Hz (20 M)
21.000 - 21.350 M.Hz (15 M)
28.000 – 28.350 M.Hz (10 M)

Frequency control :
Ver. 1: Direct Digital Synthesizer (DDS) with 1 Hz step continuously variable VFO with 20 memory channels. 2 line LCD display. Dual VFO, Split , RIT, Key pad /rotary encoder for frequency entry.

Ver. 2: 5 Band Heterodyne VFO with PIC frequency counter to reduce cost of the project.

Receiver :
Single conversion receiver with 10.000 M.Hz Cohn filter.
Low noise figure, 2.2 K.Hz SSB band width, 1.5 W audio O/P.

Transmitter :
RF O/P - SSB - 90 W (DC PWR I/P)
CW - 60 W (DC PWR I/P)
Built in CW side tone, CW delay, pwr meter, MOS FET Push Pull PA.

Dimensions :8.5 X 7 X 4.5 inches

Happy Homebrewing/ Happy HAMing

73,
VU2WSM

From my experience the loop, I had a dipole for 160 and changed to the loop and it works great on all bands with a home brew ballanced tunner. Just my opion for what its worth.

Here’s my question…

160 meter loop fed with 450 ladder line, loop is up 25 foot, loop is pretty much a square

Verses

a 160 meter doublet, 260 foot dipole fed with 450 ladder line. Apex at 50 feet, ends at 15 feet.

I run 100% QRP so which would be the best performer on 160, 80 and 40??

Have to agree on the loop.

Mine is 1000', up 35' fed with open wire line and works all bands

easily with a tuner, if I run no amp, the internal tuner in my 756 PRO

III, will tune all bands, no downside, but the fantastic up-side is the

quiteness of the antenna, at times on upper bands, it would make

you think it wasn't even connected. As always,the bigger the better.

Loop, Loop, Loop.....Mac

3290. Re Loop versus doublet Question

Yahoo group: SkyWires
Date: 2009-01-06 14:31:45 UTC
From: Thomas F. Giella KN4LF
Topic: 3290 Message: 3290

Jim,

A 2 wl horizontal loop on 160 meters is going to give you some lower TOA radiation at around 45 degrees and allow you to work some DX as well as rag chew close in. A 1/2 wave doublet on 160 meters is going to give you a TOA of 90 deg and will be good only as a rag chew antenna out to 500-600 miles. The 2 wl loop will be much more quiet on receive than a 1/2 wave doublet, a very important consideration

I ran an A/B comparison of a full wave loop for 160 meters versus a 1/2 wave doublet for about one month and the loop beat the doublet everytime on every band on 160-10 meters both rag chew and DX.

The loop is the way to go.

Just for clarification when you say a 2 wavelength antenna do you mean
2 wl for 80 meters? (560 foot).

3294. Mega-loop?? (Size suggestions...

Yahoo group: SkyWires
Date: 2009-01-10 04:03:29 UTC
From: Mike
Topic: 3284 Message: 3294

I have two one-wavelength 160 Meter antennas, both are fed with 450 Ohm window (ladder) line, and are at 35 or so feet off the ground.

Both antennas are very near trees in at least PART of the pattern of the wire's path.

In view of the fact that 450 Ohm balanced line is virtually LOSSLESS, I have had the thought that I could make up a new loop antenna, out in the clear. I have an open field where I now have two masts that are holding up the North side of my "North loop."

Using these two masts, here are some considerations:
1. I'd use the two masts that are now in place
2. These two masts are 50+ feet from a grove of trees
3. The grove of trees separates the two masts from the house
4. I would like to make a five-sided loop
5. I would like to shoot for an optimum SIZE or wire length
6. I would use balanced line to feed the antenna
7. The feed-line would be about 150 feet long

So, I have some far-away memories of a "favored length" of a mega-loop, within reason, but I cannot verify the (about 1100 feet?) length from any of my searches.

My question: What is the most IDEAL size that one could consider? My main interest is Some 160, and a good deal of 75, 20, and 17 meter activity.

My present 160 Meter loops both seem to do well on 20 and 17 Meters; With this in mind, might an even larger loop be worth the time, cost and effort?

I am looking forward to your opinions and references! (Thank you!)

-Mike-

Topic: 3284 Message: 3295

Hi Mike,

Maybe I missed the details, but how far apart are
your two (2) 1WL 160 mtr loops? How are you feeding
them?

I just joined this group, but have been using large
horizontal loops for a very long time. My personal
thoughts would be to go with the 2WL horizontal loop
at around 1,100 feet. (my actual calculations are
1,093feet (984/fMHz[1.8]=) AND put a 1 WL horizontal loop
inside the big one. You will need to ground the unused
loop and use two feedlines or a relay that will ground
the unused loop. Your wire is going to stretch so getting
it cut exactly is a waste of time. Let the tuner do the
work.

Dennis,

I looked at their website (<http://bluestarante nnas.com/ sales//catalog/ product_info. php?products_ id=391>) which says it measures 74" overall, longer than what you indicate, that it's made in USA (not in Asia). There seem to be positive reviews both on the company's website and 10 of 11 on eham.net give it 5/5. I wonder if the seller misrepresented what you bought.

Yes, I would like further explanation of the discrepancy between all the good reviews and the recent review taking the Blue Star to task ... hard to believe everyone is talking about the same antenna ...

Gaffer's Tape
Posted by: "Steve" lawresh@... lawresh
Mon Jan 12, 2009 8:26 pm (PST)
The last gaffer's tape I purchased through one of the big New York camera stores - likely B&H Photo or Adorama. The tape is labeled:
Permacel
Professional Grade Gaffer Tape
Bogen Tape Products
PP 212 B
Black
The tape is NOT duct tape. It has a higher grade adhesive that leaves little or no residue when removed. However, like duct tape has a fine cloth base. As such, it could be mistaken for duct tape -- at a distance.

Great stuff... but more expensive.

I was down there on my friends boat 2 years ago, and IIRC, one or the other of the halves of the island recognized the CEPT reciprocal licensing. I think it may have been the French half. If so, that should simplify things as I think all you needed to do was carry the right document with you and use the proper prefix.

I researched it but didn't end up doing any operating from there so the memory is fuzzy.

France and The Netherlands are both CEPT countries that recognize a U.S. ham license. You need 3 things to operate legally in St. Maarten or St. Martin. 1. Your U.S. ham license. 2. Your U.S. passport. 3. A printed copy of a 3-language FCC Public Notice which can be downloaded here: http://www.arrl. org/FandES/ field/regulation s/io/cept- ral.pdf

The procedure for U.S. hams to operate in CEPT countries is described in detail on the ARRL web site:
http://www.arrl. org/FandES/ field/regulation s/io/cept- info.html

The external "territories" of some countries are excluded from the CEPT agreement, but I believe that St. Maarten and St. Martin are NOT excluded.

When operating you would use the local prefix slash your callsign. For example, in St. Maarten you would probably be PJ7/KC0ZNT. In St. Martin you would be FS/KC0ZNT.

> them?

The loops are "close" only at the feed points, or corners. I am using a 56 foot mast, which is the almost-common-support for the two loops.

The NORTH loop's wires run North and South; The SW corner is within 8 feet of the 56 foot "common" mast. (The feed point is 8 feet NW of the support mast.)

The SOUTH loop's wires are at a 45 degree angle from being North and South. (It is like the South loop is rotated by 45 degrees, as compared to the NORTH loop.) The SOUTH loop's North-most point is within 15 feet of the 56 foot common support mast. (The feed point is 15 feet South of the "common" support mast.)

The NORTH loop's two supports that hold up the North-most East-to-West wire are about 175 feet apart. (These supports are both out, in the clear. No trees, etc. within 75 or so feet.)

I mention these two supports, as it is my foggy thought-process that is suggesting that these two masts could be used in a five-sided loop. These two supports would be on the "new" proposed loop's SOUTH-MOST side. (And, again, the "best" length of wire to use... Somewhere, I had seen reference to a 1500-plus foot loop length.)

-To continue the description of the loops, as you had asked: Each of the present loop antennas has it's own feedline:
The NORTH loop has about 50 feet of 450 Ohm window (ladder) line which runs to an Icom AH-4 auto-tuner in the garage.
The SOUTH loop has about 75 to 85 feet of this same type of window-line, which runs to a second AH-4 that is in my basement shop. (I have two operating positions in my home.)

> I just joined this group, but have been using large
> horizontal loops for a very long time. My personal
> thoughts would be to go with the 2WL horizontal loop
> at around 1,100 feet. (my actual calculations are
> 1,093feet (984/fMHz[1.8]=) AND put a 1 WL horizontal loop
> inside the big one.

It would be too big of a task for me to put up an antenna as you have suggested, I'm afraid. (I have no reference as to the added gain, etc. that a dual-loop would give me.)

On the matter of your suggestion of a TWO WAVELENGTH antenna: Is this considering a single band antenna? If this is the case, then your 1100 foot length makes perfect sense.

However, in my case, I actually do NOT operate 160 Meters very much; I mainly like 75, 20 and 17 Meters. -As such, I am already at the TWO WAVELENGTH setup, as my present loops are both at least 2WL on 75, and a lot more on the higher frequency bands.

Bottom line: Is there any REAL GAIN that an effort to make what would be a 2 WL or a 3 WL "160 Meter loop" might offer??

Maybe I am as well off as is LOGICAL, as the larger antennas (per the modeling software) indicate that the peaks and dips are a lot more dramatic as one goes higher in frequency.

You will need to ground the unused
> loop and use two feed-lines or a relay that will ground
> the unused loop. Your wire is going to stretch so getting
> it cut exactly is a waste of time. Let the tuner do the
> work.

Yes, I will absolutely use tuners!

On the GROUNDS applied to a loop antenna: I have knife switches in place at the present time, for both antennas; I have operated the two loops with and without the UNUSED antenna feed-lines grounded. I have noted NO difference on either antenna, with or without the grounded antenna feature. (??)

> KØJTA
>...snip....

Outstanding, Mike,

Great loop setup in my opinion.

The only thing I think you would gain by going to a
single large loop VS the two loops you are using now
is the bigger loop should lower your takeoff angle
for the 80 thru 10 meters and DX chasing. Well, it
would also increase your coverage with 160 meters but
if you are not working the band, there is no reason
that what you have is the best for the location.
Plus you are happy with it.....and that is most
important!

Sure appreciate your description of your loop farm.
That is real radio......to me.

3301. Calculator for "Length of a Harmonic Wire"

Yahoo group: SkyWires
Date: 2009-01-17 18:14:30 UTC
From: aa5wg
Topic: 3301 Message: 3301

HI to all:
Does anyone know of a calculator that finds the length of a wire harmonic antenna? The formula is: Length in feet = 492 (N - 0.05) divided by Frequency in MHz. N = number of halfwavelengths at operating frequency.

Or, for 1/4 wavelength data: The formula is:
Length in feet = 246 (N - 0.025) divided by Frequency in MHz.

Do you think one could include the total length of antenna "system", i.e. end of one half of antenna and transmission line, when making these calulations?

It would be very helpfull if I could calculate the total length of antenna system, in 1/4 lengths at operating frequency, to achieve a voltage or current nodes at the link antenna coupler. Do you think I can use above formula for this goal?

Any ideas?
Thank you.
Chuck - AA5WG

3302. full wave 40 meter multi band vertical loop

Yahoo group: SkyWires
Date: 2009-01-18 06:34:51 UTC
From: Kim
Topic: 3302 Message: 3302

I recently put up a full wave vertical loop for 40 meters. It is rectangular in shape and is fed near the center of the bottom horizontal section at it's lowest point with a 10 foot section of 300 ohm twin lead followed by a 4:1 balun then a 20 foot long section of RG58 leading to a tuner near the transceiver. It is a great antenna for RX but not TX since other stations don't receive me as well. I first fed it with twin lead straight to the tuner but it works better w/ balun and coax matching section.

Any suggestions how I can improve performance on TX? There seems to be a lot of conflicting information on the web. Thanks for your input in advance.

Ken

From: Scott MacKenzie
Topic: 3302 Message: 3303

How high is the feed point and the bottom of the loop? It should work well - but you may need to get it up in the air a bit. One thing is that having a vertical loop will have a low angle of radiation. This means that local stations will not hear you very well, but DX might.

From: Siegfried Jackstien
Topic: 3302 Message: 3304

if you want to have a low angle radiation it is better to feed one of the vertical sections but that is only true for 40m
how high is your feedingpoint over ground`?
my thought is if you want to use it "multiband" it would work better if you hang it horizontal
cause on the higher bands you will have a high angle of radiation
all your power is lost in space :-)

Scott,

Don't know about you but I have yet to see a full wave "vertical loop" perform very well as a multiband antenna. The Horizontal Loop does a very nice job of multibanding, but usually the vertical loop has been a single (monobander) band antenna. Yeah, you can use the Vertical Loop for different frequencies, but maybe you would run the installation on EZNEC and you see some very different lobes than you would normally expect to see from a multiband antenna. But on the other hand the vert. loop is a great DX antenna on the choosen band and it does not have to be up in the air very high.

.....Chuck, I am not sure what you are
wanting to do? Your link coupler should be able to
be parallel or series, because on different bands
the current / voltage nodes change locations along
the feedline/antenna.

One thing that I do know is if you include the
transmission line and the antenna as being the
1/4 WL, you are going to have your max radiation
at your feedpoint.....ie, the rig.

Oh I agree with you - It was my impression that this was a single band antenna (hence feeding it with a balun and coax). On 40M it would be a good low angle radiator and good for DX. It would not be good for local conversations. I suspect that a vertical loop would not be a very good multi-band antenna - for the reasons cited.

Hi Chuck,

you don't need to look for a calculator. DL7AHW did this work and
you can find his final charts here:

http://freenet-homepage.de/dl7ahw/AntennenlaengeE.html

I think this is what you look for !?

e.g. 13,50m (the first knot) = 45ft.
is a good choice for a "universal" length, not to make the
tuner/autotuner run into extremes

Hi Thomas:
Thank you for your information.
Did you try the formula from the ARRL Antenna Book?
If you have time, please let me know what you think about this formula.
Thank you for your kind consideration.
73,
Chuck - AA5WG

No formula will be able to predict the electrical length of an antenna on
harmonics. An antenna self resonant on 7.000 kc will not self resonate at
21000 kc and a T or L network antenna tuner will be needed. On 14000 kc you
will need a parallel link coupled matching network.

Hi Walter:
Thank you for your email. Yep, I am trying to calculate the high current points (low impedace points) for current feed for a link antenna coupler. I would like a high current point at the antenna coupler for my selected band.

This formula, I believe, was to calculate the harmonic length of the antenna element, i.e left and right side of a dipole antenna and not the transmission line.

Could I use this formula to include the length of the transmission line along with one half of the dipole element, i.e. left side of wire element of dipole plus length of transmission line.

....Chuck, I am not sure what you are

wanting to do? Your link coupler should be able to be parallel or series, because on different bands the current / voltage nodes change locations along the feedline/antenna.

One thing that I do know is if you include the transmission line and the antenna as being the 1/4 WL, you are going to have your max radiation at your feedpoint... ..ie, the rig.

Thanks for all your responses. I took it down and rehung it as a horizontal loop - same dimensions 140 ft circumference, highest corner 30 feet, lowest point 15 feet (unavoidable), and feed point 20 feet. So far it gets out better than the vertical loop on TX but doesn't hear as well as the vertical. I've yet to test it on other bands. So far I like it better since it's weird not being able to work stations I can hear hi.

.....end snipped.....

Hi Chuck,

Yes, you can use the formula to include the length of the feedline. For instance, please see:
"Optimizing Line Length" at this URL
http://members4.boardhost.com/NAO911/msg/817.html

This next URL has some different ways to hook up feedlines for different antennas:
http://members.tripod.com/~KE4UYP/Feed_Line.html

Or one of my favorite schemes: W5DXP's No-Tuner All-HF-Band, Horizontal, Center-Fed Antenna
http://www.w5dxp.com/notuner.htm

Maybe one of these websites will help your decision in building your antenna system.

Hello Jochen and all friends,

Happy New Year 2009 to one and all.

I had been using this antenna, which is basically a parallel square loop one on top of another fed by a sgc sg230 antenna coupler at a common point. I don't know if this antenna has any gain or other technical parameters, the wire length is 125 feet x 2 - 250 feet in total, and performance is very good especially on 7 & 14 MHz bands. I can inform everybody from experience that with sg230 in place there is lot of scope for experimentation with wires. Also can anybody tell me if I use the bottom square as a reflector by removing the connection from the coupler please?

Hi Chuck,

you don't need to look for a calculator. DL7AHW did this work and
you can find his final charts here:

http://freenet- <http://freenet-homepage.de/dl7ahw/AntennenlaengeE.html>
homepage.de/dl7ahw/AntennenlaengeE.html

I think this is what you look for !?

e.g. 13,50m (the first knot) = 45ft.
is a good choice for a "universal" length, not to make the
tuner/autotuner run into extremes

vy 73,
Jochen (DG2IAQ)

I've had the 40 meter horizontal loop up about a week and so far it's
been pretty disappointing. It's a fine antenna for SWL but inferior to
my dipole for transmitting. Also it requires some power - I've made
zero QRP contacts on it and need about 20 watts to get out. Definitely
not worth all it took to get it in the air.

From: Scott MacKenzie
Topic: 3302 Message: 3325

A good part of the issue is height. You really need to get it up in the air much higher. On 40M, the signal will be going straight up - it will be a cloud burner. That is fine for local (1000 mile contacts), but for it to play well, you really need it to be up higher in the air. The same will be true for the other bands.

Feeding with coax is fine for single band operation - but for other bands the losses will be high and most of the TX and RX signal will be lost in the coax.

I have an 80M loop, up about 50-70 feed in a lazy trapezoid. It works extremely well for 80M and 40M I use it as my low band US contest antenna. It still has a decent DX component (low angle of radiation) too. For 20M, it doesn't do as well because I am competing with people that have beams. I don't break pileups - but I can work just about anybody I can hear.

Recommendations:

First, see if you can get the loop higher in the air - the higher the better;
Second, think about feeding it with ladder line. The losses will be greatly reduced, and it will be easier to tune.

Hope that helps

Scott, aka KB0FHP

Kim
some of the answers are right but I have tried a number of loops on
both hor and vertical. My loop now is centered on 7200 and fed with
coax.I sloop my loop from 35 feet to 8 feet.and feed with a 1/4 wave of
75 ohm coax (I am using rg6 u and then with rg8x to the rig.) . I
pruned it with only 8x then put the 1/4 wave 75 in. Without the q
section it was 1:1 on 7200 . I work all bands 40-10 except 30 and 17. My
internal tuner will tune 30 but not 17 . I can tune 17 with my SA2040.
All bands are close enough to use the amp without the tuner (under 3:1)
except the 30 and 17.

Ron,

You didn't mention how well your current loop works but I imagine
pretty well since you describe it. Yours has it's lowest point at only
eight feet so height must not be so important. I guess all we can do
is experiment. The W0HMS article says no matching networks - just use
straight coax. I don't know how he came up with that since you can't
feed a multiband dipole using coax (I'd like to hear his explanation
for that). I think what works is hit or miss for any given situation.

dear jim
you wanna build the best you can ... so what about a 4-square for 40??
should be easy to errect 4 pushup-poles....
or do you want a skywaveantenna for local contacts??
last year i was able to get zl and vk from germany in ssb with only 100w and some wire
it was a very big loop so i don´t know if you have the space for bit

Hi,

Interesting, How high is your loop, how high is the dipole. How are they
fed? I am planning on putting up the best 40m antenna I can come spring
and need all the info I can get hi hi.... winter is definitely too cold ...

Sorry you are having a negative experience with the horizontal loop, however, there is a lot of misunderstood very simple things that should be used when putting up a horizontal loop. IMHO:

..forget coax feeders unless it is a monobander.

..unless you have NVIS as your prime goal, then the next band lower should be your target loop size. ie, if you want to operate 40 thru 10, then make the loop for 80 meters. This lowers the take off angle and provides way better coverage.

..if you just have to use coax for a partial feeder, ie inside the shack or entry/exit from the house/shack then please use the coax until outside, then install a 1:1 or 4:1 balun (whatever your tuner requires for the best operation) then go to ladderline, open wire feeders, or TV twinlead.

..the feed point impedances are a WIDE swing from band to band just like a dipole/inverted vee will be when used as a multi-band antenna. That is why using the ladderline or twinlead is best for less losses. If you are running QRP (like I do) then think ahead and avoid anything that creates losses in the antenna system.

..a horizontal loop is real estate intensive but you normally can put a loop up, even if it is around the perimeter of your QTH.

..I have been using horizontal loops since 1976 and the only time I have been disappointed in the Horiz. Loop is when trying to press one into service BELOW the design frequency. IE, using a 40 meter loop on 60 or 80 meters, etc. You must break the wire loop 180 degrees from the feedpoint to use the loop effectively on the

below design frequency. Then you have a bent dipole!

..horizontal loops are very good radiators even at low heights. Higher up is best, but most of my loops are no higher than 30 feet. Actually I have a GML (Ground Mounted Loop) that lays right on the ground and it works better than a Grasswire Antenna.

..wire size is no big deal, but the bigger the loop then you either need stronger wire or a lot more supports. Most of the time #14AWG will work fine until you get to over 500 feet. You have less loss but more weight when going over to #12AWG but that is what seems to work best when going over 500 feet in the loop length.

..feed point, don't feed a multi-band at the corner unless you don't mind a rhombic antenna effect on the upper bands. Most of the time feeding at the middle of one side is just not convenient but you can feed it maybe 10 feet from a corner to avoid the rhombic effect.

..always look for a better way to enjoy a Horizontal Loop. The collective effort of all of us has yielded some fine mods and fixes. The more you use and experiment with Horiz. Loops, then the more you will giggle at some of the articles in magazines and online.

That's my story.....and maybe I'm sticking to it....Grin!

I don't have Walter's experience with the horizontal loop, but I totally agree with K5EST's points. Since I now primarily use mine on 160, and since it is a bit short for a full wavelength on that band, I'm thinking about breaking it about halfway around and seeing what it looks like as a "bent dipole."

Mine is 15 feet above ground in some places, 35 feet up in others. This weekend on the 160-meter CW contest, I worked every station I called on the first or second call but one (never did get him...he was in Arizona and deep in the QRM), and they were from Manitoba, Canada, to California to Prince Edward Island. I was running 100 watts.

I've also worked Europe and Chile on 160. But the truth is, I don't even hear a lot of the DX that guys with verticals, inverted Ls and high dipoles are working. I just don't have the height.

Hope you figure out what is ailing yours. The loop is no miracle antenna, but it is a very good one. It allowed me to get on 160 without a 270-foot-long dipole, which I could never have fit on my lot...without bending it!

Hi Don,

Thanks for the nice comments. If I could mention,
please separate the halfway around break in the
wires about 2 ft (24 inches) minimum. Some guys
have had good results with just using a couple of
egg insulators in-line as the gap, but lately I
have been using a piece of PVC pipe of 3/4 inch
size that is 2 feet long with holes drilled in the
ends for the wire tie holes. It could just be my
homebrew tuner that doesn't like the high voltage
points so close together, so I went for more
separation of the ends.

Sure would appreciate your thoughts and experiences
on this detail.

Happy Horizontal Loops to you!

Hi Walter,

I really enjoyed reading ur post. I am presently planning some antenna work for the spring and some of my ideas overlap with some of the things you said. Here is my situation. At the moment I have a single band, 20m rotatable dipole element made of aluminium tubing mounted on the top of my 55' tower fed with RG-232 coax cable. It is very efficient and effective ... even at QRP levels (lots of DX). The problem it is mono band.

I want to operate 40m as well as 30m and 15m. and it would be very nice if I could do it all with one antenna .... although I will probably continue to spend most of my time on 20m ... my favourite band (probably because it is the only band i can operate hi hi).

Back in the old days .... (late 50's) I used a vertically oriented loop for 20/15 (actually 2 loop elements in a quad arrangement) mounted vertically with the centre at 30'. It was very effective .... I really like the loop ... as it was really nice and quiet as well on receive. In my present situation I have a really nice tilt over tower in my front yard a few feet away from the front of the house. It tilts over and comes down into the side drive. A big box antenna like a quad won't fit .... whereas the dipole comes down almost to the ground making working on the antenna a snap.

In all of the alternative arrangements I have been thinking of I would feed the new antenna with 450 ohm ladder line and bring right into the shack ... where I have an excellent balanced antenna tuner. I want the antenna to be useable 40-10M

Plan #1
However if I were to construct a 20m loop (single element) the dimensions would make it approximately 17.5 ft square. If I mounted it vertically and rotated it so it was parallel to the side of the house I could bring it down to the side drive and the mast would be about 8-9 ft from the ground. I could easily work on the antenna with a small step ladder.

Plan #2
I could mount the same loop in the horizontal position and physically I would be in the same position in terms of access when I bring it down into the driveway and have access to all parts of the antenna from a small step ladder.

Hi,

For what its worth, I read an entry in an old ARRL antenna hand book concerning the performance of a 1/2 wavelength loop. First it is self resonant with a different current distribution than a full wavelength loop. One side of the loop is high current and the opposite side is low current. They made the point that this current distribution remains the same and thus performance whether it remains unbroken except for the feed point or open at both the feed point and directly across from the feed point. In the first instance (unbroken) the feed point impedance is high ... eg up to 2000 ohms, while the impedance drops to the 60 to 100 ohm range if the loop is broken across from the feed point. The important point is performance remains the same ... just the feed point impedance changes and the slight directional characteristic reverses.

The second interesting point they made was that the radiation pattern will demonstrate a small directional pattern since there is uneven current distribution. The directional pattern reverses when the loop is broken across from the feed point.

Later issues of the handbook seem to have dropped the discussion of the 1/2 wave loop.

Hi Jim,
Boy, I have no idea why the handbook does not include
the 1/2WL loop, but there have been a lot of guys that
are trying to make it a multi-band antenna and to me
there are way better antennas to put into the air.

.....top reply.....
..

Hi Jim,

Glad you have the tilt-over for a mast. With your house
being that close and still wanting to be able to service
your antenna (you are a wise man), then my first thought
would be "Go with LB (W4RNL-now SK)" and use a 44 foot
metal dipole fed with 450 ohm ladderline. The 44 ft dipole
will allow you to rotate and gain some escape of QRM
plus a little directivity. The advantage of the 44 footer
is that you still have radiation broadside to the antenna
from 40 thru 10 meters. Yeah, it is a bit of a compromise
antenna on 40 meters but with your height for the antenna
then you may not notice adverse problems. And best of all
you still retain your 20 meter hangout.

Maybe you have another area in the yard for a horizontal
loop.......even around the house eves. That would give
you 2 antennas to A-B switch for the best performance.

You know, if someone had the software and the time and the interest (I only have the interest!), it might be a good exercise to model a 470-foot loop, one that is roughly rectangular in shape, fed in the middle of a relatively straight stretch with 450-ohm window line. Then break it along the leg opposite the feedpoint by varying amounts of distance. Maybe varied from an inch or so up to ten or twelve feet. I mention 470 feet only because that is what mine is!

We love our loops, but there might be advantages to opening up the other end a bit. Would it behave more like a dipole? That is, would it present high reactance on even harmonics? Or would it keep the better aspects of the loop? I also wonder about the pattern, especially on higher multiples of the fundamental frequency.

Would I be better just walking off 135 feet in each direction from the feedpoint and cutting the loop there, tying off the ends, and making myself a true bent dipole? It would be 100 feet less wire in the air, but that is the stretch of the loop back there that is the highest above worm-infested dirt.

Good advice Walter. I already have the necessary aluminium tubing to extend the dipole. Your right, the 44 ft dipole length does provide a consistent radiation pattern on all bands 40-10m. The ladder line feed will then easily accommodate all band operation with good efficiency. If I do try the loop it will not be at the expense of the dipole ... I can simply put the dipole on the roof of the carport ... ready for re-installation if needed hi. I have enough aluminum to make a frame for the loop. Since my tower comes down into the drive changing from the loop to the dipole would be a week-end project hi

Hi Don,

Hee hee....great question. I don't have the software,
and being on dialup, I am not likely to download the
full EZNEC program.

All I can say is from some experience with opening up
the loop for Below the design frequency ops. I tried
the open loop "bent dipole" on some other bands and
immediately had the same high noise on receive that
my NVIS dipoles were experiencing so the loop was
re-attached.

Along with your "opened loop" modeling, it would also
be nice if some kind soul would model the feedpoint
impedances when the feedpoint was moved from say the
corner of a loop to various locations along the one
side to about midway of the side. If you are familiar
with the clothesline antenna, there are many changes
in impedances along the sliding feedpoint.

try out mmana ... it is a modelling soft that is easy to use (and freeware)... you will find that the loop is better as the bent dipole ...

With a loop fed at the top of the 55 foot tower, and spread out in a delta fashion with the ends about 15/20 feet in the air - it will be a very effective antenna. I am using one now (80M loop) and am using it from 160-6M. Not as good as a beam, but it works well. It should be MUCH better than the dipole. Feed it with ladder line and you will do much better.

Hi Scott,

The aluminium material I have on hand will allow me to construct a frame that will support 70 ft of wire (full wave at 20M) in a square shape. The square is about 18 ft on a side. It would be supported with the center 55 ft above ground. The top of the square would be about 8 ft higher and the lower part would be 8 ft lower. I would feed the antenna with open wire line use it multi-band from 40m to 10m.

I know it should be as good as or better than a 20m dipole at the same height ... but I have no idea what it will do on 40 m where it is a half wave loop or on 30m where it is in between hi. It will load alright on all bands.

I could also design the frame to hold the same loop in a horizontal position at 55 ft. I have heard much comment on how effective a horizontal loop is ... but all of the examples have been in the 160-80 mtr full wave size and thus close to the ground relatively speaking. I don't know what the prediction for radiation pattern would be if the 1 wavelength loop was held at a 3/4 wavelength height above ground ... I suspect that at that height the vertical orientation might be more effective.

I should become acquainted with antenna modeling software to see if it can give any indication of how they would compare ... winter lasts pretty long here which should give me lots of time to work on the ideas hi hi

why not put an elevation rotor in your construction??
you can turn from vertikal to horizontal (and all in between) in a few seconds while receiving the other station .... when conditions change (or the range to the other station is different from the station worked before) you turn your antenna ..... local and dx in one antenna tuneable to almost any band
i think that could be very fine
if turned to vertical feed it in one of the vertikal corners NOT on the lower or upper corner
maybe i have the time to make a modell in mmana

I use MMANA - I would be happy to model a 20M loop in the horizontal and vertical planes for you. Shouldn't take me more than a couple of minutes to do. Give me your email address and I can send it to you off-line.

But if you are going to the trouble of making a 20M horizontal loop - you might want to consider a Moxon - nice gain and F/B.

What an interesting idea. I am always coming to my local black smith with new fabrication ideas. If not a rotor .... some kind of manual hinge that can be shifted 90 deg.

My tower is hinged at the 18 ft level and is an easy one person operation to bring down into the side drive (using a bloc and tackle). I will be feeding the loop giving it horizontal polarization.... when in the vertical position ... It would be a simple operation to feed the square from the side to produce vertical polarization. I have no idea what the polarization is if the loop is in the horizontal configuration.

if it is horizontal the radiation wil be horizontal but turned 90 in orientation
say vertical in in east west direction mounted it shoots to north south like a dipole would do
actually you have 2 close spaced verticals fed in phase
now you turn it to horizontal it shoots now east west in horizontal polarization

Looking at the models just completed - a 20M vertical loop, fed at the bottom is not bad at all. I like it better than a horizontal one .... much more low angle and very little high angle.

3350. Advice for a 2mhz loop ?

Yahoo group: SkyWires
Date: 2009-01-27 20:53:33 UTC
From: chas
Topic: 3350 Message: 3350

I have a building out back, 24x30' and I am thinking about attaching a 3 or 4' piece of 1" ID PVC vertically on each corner and wrapping the 108 linear feet with some 22 or 24ga wire... spaced about a foot apart. that would give me about 400' of wire going into some 450ohm ladderline, thence to a balun to drop it to 50ohms and then into the Dentron tuner. this is obviously going to be a cloud burner unless I can get it up into the air and away from the ground. but heck, unless I can stand it on a side AND up off the ground, it is going to be highly NVIS anyway.

I am really looking for a quiet, 2mhz antenna for 500W or so MARS work at night when the critical freq drops into the mid or low 2's.

suggestions??

Hi Scott,

Interesting observation. Your modelling software seems to be very useful. I assume the statement basically demonstrates that a 20m vertical loop, fed at the bottom and at a reasonable height of 45 ft at the center, performs better (e.g. low angle radiation) than if it was oriented horizontally at the same height.

How does it perform compared to a dipole at the same height? Years ago I used a cubical quad on 20m mounted on a 30ft TV mast. It was a great DX antenna. I am sure the second element (reflector) must have lowered the radiation pattern. I don't have the space for a quad ... but a single element might be possible. I wonder if improvement would be sufficient to justify replacing a straight dipole element.

I wouldn't mind looking at antenna modeling software myself ... any suggestions on how to get started ?

The Vertical loop performs better than a dipole at the same height. I guess I need to put a quick and dirty presentation together and post on the files section.

Regarding modeling software, I would strongly recommend MMANA because it is free and does a pretty good job. I have found it to be reasonably accurate. It can also take advantage of the NEC 3 engine. If you want the ultimate, use NEC 4 - but be prepared to pay the big bucks. NEC 4 does a better job of handing verticals and ground interactions.

http://mmhamsoft.amateur-radio.ca/mmana/

I personally like it - and it is relatively easy to use.

Thanks Scott,

Good info ... I will check out MMANA for a starter.

In the mean time I found an interesting on-line 'height vs elevation'
calculator for dipoles, horiz. and vert. loops, and inverted Vees. I took
the height of 50 ft (what I have to work with) which is close to 1 WL at
15m, .7 WL at 20m, .5 WL at 30m and .35 WL at 40m. and compared the
elevation angle of radiation of the dipole vs a vertical loop.

I found the results very surprising. The higher the antennas in term of WL
the less the difference. e.g. at 1 WL the vert loop has a lower elevation
by only 1 deg. At .7 WL the difference is 4 deg. At .5 WL the difference
increases to 7 deg, and at .35 WL the difference is a whopping 16 deg !

However the horizontal loop does not show this trend. No wonder the
vertical loop is so popular on 40m for DX given the dramatic improvement in
elevation angle over a dipole at the same height. However I understand the
popularity of the horizontal loop for 160m and 80m since it is very
difficult to construct a vertical loop at these frequencies.

Hi Chas,

Not sure your 4 turn loop is going to do the job for
the intended use. My guess is that a single turn
horizontal loop 4 sided would do a better job.
Probably will not need the amp at 2 MHz, but who knows!

At your low elevation, I doubt that modeling the antenna
is going to be reliable, at least EZNEC can't do it
but maybe the other program can do the reliable calculations.

I am all for experimenting, please let us know how / what
you come up with for the 2 MHz loop.

dear jim
look out for mmana ..... it is freeware and can be found here:
http://mmhamsoft.amateur-radio.ca/mmana/index.htm
there are lots of antennas in the "anf" folder
the soft is easy to use
and if you have the same soft as i (and scott) have .... it is easy to exchange modelfiles
if you have questions how to use it feel free to ask
and you should join the yahoogroup "mm-hamsoft" .... there you will find others that are using
the soft.....
you should also try out the other soft from macoto mori .... mmsstv mmtty and the dspfilter
the dsp filter is very good :-)
i have allways connected my trx to my soundcard for the digital modes .... if you have a qso
nearly in the noise the dsp-filter is started with a mouseclick .... you can programm userfilters as well

thanks for the reply Walter

of course, this loop would be attached to the roof fascia boards and extend above the hip roof's edge. but again, this is just too close to the ground. better would be some bamboo poles radiating from a center axis attached to a 20' mast above a 50' tower... rotatable even <G>. I guess I better be happy with my 140' Cobra at about 45'... this IS for MARS use across the state of Texas. That is 420' of wire but not a spread out loop. maybe I need to study the trees around the property some more <G>

Hi Chas,

I was not concerned about the height of your antenna
as far as radiation, my concern is the 4 turn loop.
Some of those 'big coils' have not worked for me in the
past. You ought to be able to blow the speakers off of the
shelf at AAA6TX's QTH with a 4 sided full wave length
horizontal loop fed with ladderline (since you are using
an amp).

ZUI
http://www.wd8das.net/160loadedvee.jpg
Bet you could do some good with this antenna but it is
not as good as the full wave horizontal loop.

Walter
I understand the multiloop... the 50' coil might be an idea for a single loop around the roof, shortening the straight line, increasing the coil. I am trying to guestimate a tuned dipole length for a mid 2mhz and I think we are talking about just under 400' - to round it off. I assume that the coils are simply a way to shorten for lot constraints, the length of the illustrated dipole. iow, straight line vs coil are 1:1. so, I could probably use multiple coils? to achieve 400' single lap around the roof...?

if it is horizontal the radiation wil be horizontal but turned 90 in orientation
say vertical in in east west direction mounted it shoots to north south like a dipole would do
actually you have 2 close spaced verticals fed in phase
now you turn it to horizontal it shoots now east west in horizontal polarization

What an interesting idea. I am always coming to my local black smith with new fabrication ideas. If not a rotor .... some kind of manual hinge that can be shifted 90 deg.

My tower is hinged at the 18 ft level and is an easy one person operation to bring down into the side drive (using a bloc and tackle). I will be feeding the loop giving it horizontal polarization.... when in the vertical position ... It would be a simple operation to feed the square from the side to produce vertical polarization. I have no idea what the polarization is if the loop is in the horizontal configuration.

>.....end snipped.....

I don't know about the loaded horizontal loops as being
good performers, Chas. My luck has been unfavorable but
there is always a chance the loaded loop would work
satisfactorily for you. Since you are using it mainly
for the 2 meg freq then maybe it would be possible to
keep the loading coils not at the high current areas.
This is not my cup of tea.....Grin

My notes on several multi-turn loops are showing that
the best that I could get to work (without computer
modeling) was a 3 turn loop, vertical mounted, and
with a L-match at the feedpoint which was at the
bottom of the loop (closest to ground). This was one
of the few times I slipped up and actually used coax
for something!

You might be interested in drooling over W6OBB's loop
farm which includes a 2 turn horizontal loop. I can
guarantee you his loops work flawlessly.
http://www.smeter.net/w6obb/antenna-farm.php
and
http://www.candlewater.com/3830/artsloop2/

Oh yeah, before I forget, I sent you the loaded
dipole URL so you might consider that antenna if
you cannot get the room for a 2 turn horiz loop
or better yet.....in tune with this reflector
a full wave horiz. loop.

Thanks for bringing this thread, maybe someone
else can chime in and help us with some experience.

I have uploaded a pdf file of a reference dipole; 20M horizontal loop and a 20M vertical loop, fed with 50 ohm coax, and fed in different positions. All are modeled at 10M high, with the center of the antenna being up 10M. Let me know what you think. The file is a bit big at 4.8 Mb, but I think you will find the information useful.

Hi Scott

That is really enlightening information. I will have to investigate that software and learn how to use it. I would like to know how the same vertical loop (20m) performs at 15m height on 20m, 15m, as well as 30m. The charts you developed demonstrate an appreciable difference in DX performance (elevation angel) between the vertical loop and the dipole. I suspect the difference would be less with the antennas at the 15m height.

Thank you Jim:

Actually what slows me down is getting the images into Photoshop (to make the images and crop out extraneous data) and then to put it into Powerpoint. Then double checking to make sure I got the right file with the right height, direction or feed-type....

Hi Scott,

I am impressed with how fast you can turn out the data. I have downloaded all your files and I am using them to help make up my antenna plans for the spring season.
The diamond shape has a number of advantages. As I mentioned there is a problem bring larger structures down so they fit the structures on the ground (unlike the 5 acre antenna farm hi hi). Planning is a lot of fun .... one physical solution is to make one of the 'wings' of the diamond 'foldable' when lowering to the ground.

> **

and that is really all that I want to be able to do.
a couple of questions Thomas,
== is your loop oak tree supported? that and pecans and other is all
I have to support a loop (horizontally) around the perimeter.
== is your loop wire insulated ? same above to cut down on leaf, etc
grounding.

Art Bell is able to put up hellacious high support poles because he
has several acres of bare desert land. However, a lot of us might
think that he lives in hell and we much prefer our trees surrounding
our little oasis of light ... a glade in the forest containing our ham
shack aka home. hi!

I know of a lot of hams who live in piney woods running non-loops
which zig zag from tree to tree and who put out very fine signals,
barefoot. I really believe in lots of wire, as high as you can get
it.<G> But I do not run bare wire. I run insulated products like my
140' Cobra or my DX-CC in the belief that the insulation reduces
grounding. aar, I have one of the strongest stations in Texas MARS
with my HK SB-220 amp and my 50' high dipoles down here on the coast.

thanks

I have a 500 foot loop running thru the trees at 20' to 8' above ground... it's made of #14 insulated wire... the kind you get in spools at Lowes. It works fine. I live in a deep valley and a cloudburner is the ONLY way I'm getting a signal out of here (NE Tennessee.) I've talked to Oregon on 80, California on 40, Nova Scotia and Canada on 40 and 20... not so much on 10. The take off angle lowers each band you move up from the resonate freq. with a horizontal loop, so the mountains at blocking me.

Use insulated wire if you're running it across limbs, (non-metalic) shingles, etc...

Use un-insulated if you are in the clear. At least this is what I've been told in the past by my Elmers.

Take care,

Steve, W4HKL

Hi Guys,
I'm using a 290' bare copper wire Horizontal Delta loop that contacts several trees, with no problem at all. I use legal limit power when I feel like it and haven't started a fire yet !
I will concede that rain and/or snow noise will probably be better with insulated wire. Come spring I hope to do some multi-band loop testing, it's been cold and lots of snow here in Indiana. I have some very good ideas I want to test. Will keep the group posted.
73 all, Ace

From: John Berry.
Topic: 3387 Message: 3387

Hi All,just found and joined the Group.I have a fairly long garden,about 60ft,and a fairly high House about 50ft.Masterplan was to run a wire from the Shack,middle floor,about 25ft from ground,up 15ft,down garden,60ft,down pole 40ft,back down garden,60ft about 6ft off ground,then back up to shack 25ft.The Loop would be Vertical,estimate about 200ft of wire.Read for Top Bamnd 160mtrs the need to keep the current of Ant' out in the clear ??.Main interest are 160/80/40mtrs.Both ends of loop would go sraight into ATU in shack,no feeders involved ??.Any comments/suggestions welcomed.John G1WOS.Bristol UK.

3389. 80M FW height vs Performance

Yahoo group: SkyWires
Date: 2009-03-19 00:47:23 UTC
From: captcurt2000
Topic: 3389 Message: 3389

Good Evening All:

I'm getting ready to put up a FW loop for 80M. I plan to use 450 Ohm Ladder Line all the way to the balanced tuner.

Problem is I cant get it very high. perhaps 20' at two of the 4 corners and 12-15 at the other side.

How much should I expect the performance to be degraded by this low height? I have heard mixed reports about these things working really well as low as 10' gutter height on a ranch style house.

Thanks

Curt

From: Scott MacKenzie
Topic: 3389 Message: 3390

It will work well on 80M as a NVIS antenna and good/excellent for short hop out to about 1000 miles or so. 40M it will be much better and much lower angle of radiation.

I use one hanging in the trees up 70' at one end and 50' at the other in a rough trapazoid. It works very well. Similar observations except more low angle on 80M and much lower on 40M. The antenna was put up as a sweepstakes antenna just for working the US - and it does very well at that. It also works well for DX on 40M and I have worked some good stuff on 80M. It also works well on 20M.

Scott

3391. 160M Loop going up this weekend

Yahoo group: SkyWires
Date: 2009-03-20 04:13:25 UTC
From: Aaron
Topic: 3391 Message: 3391

I have no idea how well this will work but since I have the wire and the space I am going for it. The height from the ground will be any where from 40' to 60', it will be level just have a steep grade from one end of the yard to the other.

The configuration is like a D shaped trapezoid with the longest side being about 230-240' long. Antenna will be constructed with 14G insulated stranded and feeding it with 9913 for the moment. I would love to use ladder line but it is just not doable at my QTH. I am still not sure exactly what the other options are for feeding it but I guess I will find out soon enough. Might even consider a remote tuner if it works as well as everyone says they do.

If anyone has any suggestions or comments before I put this up, I would love to hear them.

Well considering my feed line goes into the wall and comes out in the crawl space then pops though the side of the house. After that it would have to go underground about 50' and pop out next to a 18'X32' metal pole barn.

I could get a little creative but that will require a 4:1 balun or a remote tuner. I am thinking that the remote tuner is what I want at the end of the day but I am still waiting for my money tree to bloom.
So for now I will just deal with the loss in the coax until I can feed it more efficiently.

The 2 biggest resources I found on this just replied back... Thank you Tom and Dr Ace for your wonderful publications on the internet. Some of the best antenna stuff I have read yet.

One of these days Dr Ace I may just have to meet you, I live up in Monrovia so we are basically neighbors as ham radio goes.

Regards,
Aaron

Hello Aaron,
Yes we are neighbors. We should get on 75 mtrs some evening, and everyone in the group is invited to join the QSO. We could have a discussion about loop antennas.
If I were in your situation my first choice would be to go with a remote tuner located at the antenna feed point. I would also be on the look out for some cheap hard line coax cable. If you have a local club that is a good place to start asking/looking for it. You might be surprised at what people have laying around. A while back the Bloomington IN ARC acquired a bunch of cheap hard line coax cable, I don't know if they have any left.
As a foot note I will mention: Many small cable TV companies are a good source for FREE or very cheap hard line coaxial cable, It will usually be 75 ohm coax. This is NOT as bad as many amateurs might believe. Especially if there is a long run of feedline involved from the station to the antenna.
Very 73, Ace

From: Aaron
Topic: 3391 Message: 3399

Well, I got the 80M Dipole moved across the yard which will be the feed point for the loop. Also got all the fishing string shot up in the trees so tomorrow all I have to do is pull wire around the perimeter then hook the ropes to the fishing string and pull it up. I had to scrap the 9913 and run regular RG8. Seems to be an issue with it somewhere as it is showing 60 ohms with a load on it and the MFJ said 10DB loss at 3.5 Mhz. Something is not right with is and I don't have access to a TDR to find the bad spot.

Moving along I am excited now and look forward to getting this beast up on start working some DX. Will have some pics soon.

Dr. Ace, not sure where you hang out on 80 but I usually catch up with the Roundtable Group which can be found some where between 3803 and 3806. Rest of the time I on 3580 doing PSK.

why do you have to go underground with your feedline???
should be possible to hang your windowline at a height of 2-3m in the air (not cutting somebodys head *g*) ..... if you could hang your feedline in the air instead of laying underground you could use ladderline and so you have a multiband antenna with almost no losses .... would be better for allband ...
see the file "loop.xls" in the filearea
this is an excelsheet what i made for the swr of my loop ....
it is a fullwave for topband
i feed it over a homebrewed balun 1:9 and 2 different lenght of ladderline ....
1st run is abt 18m from the feedingpoint to the shack ...
another 20m is added just with 2 bananaplugs ...
on most bands the swr is so low that i need NO tuner at all
on the rest of the bands the swr is lower than 1:3 so the internal tuner of the rig does the job
or when feeding with pa ... the pi-section of the pa will tune the antenna easy ..
think about a better way for your feedingline :-)

Well considering my feed line goes into the wall and comes out in the crawl space then pops though the side of the house. After that it would have to go underground about 50' and pop out next to a 18'X32' metal pole barn.

I could get a little creative but that will require a 4:1 balun or a remote tuner. I am thinking that the remote tuner is what I want at the end of the day but I am still waiting for my money tree to bloom.
So for now I will just deal with the loss in the coax until I can feed it more efficiently.

The 2 biggest resources I found on this just replied back... Thank you Tom and Dr Ace for your wonderful publications on the internet. Some of the best antenna stuff I have read yet.

One of these days Dr Ace I may just have to meet you, I live up in Monrovia so we are basically neighbors as ham radio goes.

Regards,
Aaron

Aaron,
I usually hang out around 3.658 + or - 10 Khz. But I can easily move up the band let me know if you get the loop up this weekend.
Very 73, Ace

Ok, loop is up and works I guess. Seems to be resonant around 2mhz with about 70 ohms impudence from what the MFJ is saying. I checked the resistance ant the conector here in the shack and its about 1.5 ohms across the center to the shield.

That being said it tunes 160 - 6 meters on my little Dentron Jr. Monitor with the exception of 17 meters. I can get 17 to load but I have to bridge from ground to one of the balun post. Still have a bunch of QRN from a couple of things in the house and power lines.

All in all it works great but I guess I have some room for improvement with the feeding. Not too sure if getting 160 down below 2:1.

Also will note that on 40 I am getting RF back in the shack so I may have to get put a choke out there in between the house and the feed point. I am looking for a SGC remote tune so maybe that might solve some of the issues.

Ok, I just found out how to run balanced line. Had a good QSO on 17 discussing the matter. Learned something new today.... I guess I can use 2 runs on the same type of coax and just use the center conductors from what I was told.

Now I know that will not be efficient as true twin lead but this will resolve the routing issue. Any thoughts on what the best way to match this is if I go that route? Or using the remote tuner still maybe a better way to go... I don't have any issues manually tuning an antenna unlike some of the newer hams I keep bumping into.

My current tuner usually tunes about anything I through at it but I think at the end of the day I will want a dedicated tuner for the antenna... so the L vs the T or remote??

Aaron,
How many feet of wire is the loop ?
Also I added a file to the picture section of
http://groups.yahoo.com/group/SkyWires/photos/album in Dr.Ace's
Stuff<http://groups.yahoo.com/group/SkyWires/photos/album/267129049/pic/list?mode=tn&order
=ordinal&start=1&&dir=asc>
It shows how to make a simple choke balun.
If you want to test that antenna on 75 mtrs , I can get on the air anytime
before 8 PM CST or after 10 PM CST "Local Time" tonight.

Very 73,
Ace

Hi All,
If you take two identical pieces of equal lengths of coax, lay them side by side and solder the shields together at both ends. Then use the two center conductors as though they were twin lead or ladder line. This raises the impedance value of the line to exactly double its original value. If you use two pieces of 50 ohm coax then you have a near perfect match to a full wave loop antenna at the fundamental frequency! And, your coax is impervious to nearby metal objects such as gutters, aluminum siding etc.

If you move up to harmonic frequencies, then this no longer applies since the 100 – 104 ohms of the coax is only good for the design (lowest useable) frequency.

You still need a tuner between your 50 Ohm transmitter and your "shielded twin lead" feed line for multi-band operation.

Aaron, I think a remote tuner at the antenna feedpoint is a better option for what you want to do.

Aaron,
Not knowing the length of antenna wire you are using I can only come close in my calculations. But I think the antenna would tune better if you could possibly add about another 43 feet of wire to it. Maybe you could pull the center of the longest side back to or into the tree line ???
Just my 2 cents.

Ace, the antenna works fine. I have worked a bunch of states and quite a few counties on it so far. Seems to do really good. In fact I was on 17 earlier today and forgot to turn the RF power up after tuning up so I was about ¼ way through the QSO when I noticed I was only doing about 3 watts and the guy in Oregon had a solid S8 copy on me.

The best guess I can come up with on the length is just a little over 500' as a real close estimate which would fall just right in line with what the Analyzer says being resonant at 2 mhz. I was mistaken in my previous post, reads 2.3:1 at 1.990 mhz @ 30 ohms (that's what seems resonant). I can add more wire and left some insulators up there in various parts of the antenna. I actually used them for tag lines so I could pull the antenna out and over from the limbs. But I see what you are talking about if I get it tuned to 1.8 the harmonics will start falling into place thus making it easier to tune. Its close, but needs some tweaking me thinks.

Anyways I'll keep my eyes peeled for a SGC at Columbus this weekend, if not I'll build one with stepper motors. Looks like I will be in Loop optimization mode for some time now. Guess this week I'll try to add some wire somehow and the 1:1 choke then note the changes.

Hi All,
For the record, my rough calculations indicate that adding 43 feet of wire
should drop the resonant freq to a little below 1.843 Mhz.

Dr. Ace's note about side-by-side coax runs to mimic a balanced line is quite correct. Except where he says:

> If you move up to harmonic frequencies, then this no longer applies since
> the 100 - 104 ohms of the coax is only good for the design (lowest
> useable) frequency.

Unless I misunderstood what he's saying ... the dual coax still works correctly and still looks like ~100 ohms differential, it's just that the antenna might or might not present such a nice impedance on its harmonics.

Not sure why you get SWR=2.3:1 at resonance with 30 ohms. Seems to me it ought to be 50/30 = 1.7:1 if it really is at resonance. Then again, some say the MFJ shows higher SWR numbers than it should. But that would be a bad miscalculation.

I'm guessing the low impedance is because the loop is horizontal and close to ground.

Andy

Hi Andy,
Yes I knew after I posted that I should have been more specific. But I was tired and thought oh well.
The dual coax will work correctly and still look like ~100 ohms differential at any freq, it's just that the antenna might or might not present an awkward impedance to the feedline on its harmonics.

3414. Resonant vs Non-Resonant Loops

Yahoo group: SkyWires
Date: 2009-03-27 14:26:31 UTC
From: Mark Brown
Topic: 3414 Message: 3414

I've been using a loop for several months now with better than expected results; but wonder if things could be even better. Is there a fundamental advantage to using a loop that's resonant versus non-resonant?

Following the adage of using the biggest loop that will fit as high as possible, here are the general details. Length = 467' mostly square but tilted toward a parallelogram such that feedpoint is near SW corner with the opposite corner pointed NE. The open-wire feedpoint is about 13% away from the corner to give a closer run to the shack. Corner heights follow existing trees from 70', 55', 40', and 35' over sloping ground.

EZNEC modeling shows lots of variation in lobes, nulls, and gains at different elevations - as expected from the different heights above ground; and wildly varying impedance values across the different bands. There's an in-ground pool with lots of cement in the middle and have no idea how to inject that into the model.

Being non-resonant, the shack T-network tuner gets a good match on all bands through 45' of feedline. Subjectively, this antenna outperforms an 88' doublet oriented NS at 70' on almost every signal heard & worked. There's a big lobe on 40m that covers the Madiera Islands over to Ukraine on 40m.

Lengthening the loop for resonance on 160 is out of the question because there isn't any more room; but I could shorten it to full wave on 80m. My gut tells me to leave it alone. Looking for comments / opinions.

Lastly, I want to thank KB0FHP & WH2T for their excellent articles in the Files section of this Group.

73,
Mark

Sounds like a fine horiz. loop to me. If it is loading and working.....my thoughts say, leave things as is! Gosh, a resonate antenna around my antenna farm has been absent for many years. And another thing to consider, you may, by shortening your loop get into a length that is going to be hard to tune and on the upper bands you could sacrifice some of the large lobes you now have.

The thing to experiment is the feedpoint. By moving the feedpoint your lobes will change on different bands.

Just my thoughts!

Hi Mark'

Resonance does not make a loop radiate any better than one that is
non-resonant. The statement refers to large loops (wires as well)... eg at
least a 1/2 wavelength or larger. Resonance by definition simply occurs
when the inductive and capacitive reactance cancel leaving a simple feed
point resistance. In the case of the loop that resistance in the vicinity
of 100 ohms. It will vary to a degree depending on the loop's relationship
to ground. Since most people operate many frequencies and bands their
antenna operates off resonance more often than not. All that means is the
feed point impedance will become more complex including inductive or

capacitive reactance. It also means a large swing in SWR. If you use a low loss feed line with an effective coupler at the rig the system will remain efficient.

The size and height of the loop of course makes a difference.

Topic: 3391 Message: 3418

Ok, I updated the layout...

http://groups.yahoo.com/group/SkyWires/photos/album/836998787/pic/257966228/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc

...nothing a little work with Google Earth and Visio couldn't draft up. The dimensions are farily close but I know its not exact, the blue lines indicate the 80M dipole that became the feed point for the loop.

Now back to adding wire subject, I think I am stuck with what I have because if you look the drawing... I can't pull more out more NW because it would be in the neighbors property. Plus there more trees now, the image from Google Earth is probably 4+ years old and things have grown up around here, plus the barn is there now.

If I tried to pull more out from the splice point over the house I think I will be getting too close to the transformer and there is that tree between the barn and house.

The SW part has too much foliage in the way, means I would have to wrap around about a 100+ year old maple tree.

Now, if I was going with a long wire I could go back about another 200' west but its pretty thick back there for putting up a loop.

Ordering a SGC 239 tomorrow and will mounting it at the barn. So if I put the tuner out there below the feed point. What would be the best way to feed it from the tuner?? More coax to a 1:1 or just run 450 ladder? Excited now since I will have more feeding options now knowing the SGC will do it :) :)

After I get this all dialed in I am toying around with the idea of making a feed point switch and add 2 additional feed points to the loop at the splices. Sounds like a fun loop project to make the loop have 3 remotely switched feed ponts.

Hi Aaron,

Use 450 ohm line between the loop feed point and the SGC coupler. Role about 20 ft of the coax and 20 ft of the DC supply line into a tight coil close to the tuner. The coils will work as RF chokes preventing RF on the coax feed line and dc power line between the coupler and the radio. You can hold the coils together neatly with some electrical tie wraps. I use this system with a SGC 239 mounted just inside the basement window. I have 55' of 450 ohm line coming down from my rotatable dipole. The antenna tunes like a charm with the SGC 239 .... the coax routes across the basement to the other side of the house and the radio shack. The dipole is 40' long and loads nicely on 40-10m with the ATU. Ideally the coupler should be outside up at the feed point ... but the SGC 239 is not weather proof and it is so much more convenient to have it just inside and out of the weather.

Jim,
I will be mounting the 239 in a WX proof box out at the corner of the barn. I have and extra Dish standoff mount that will be mounted at the eve of the barn roof. So I am only looking at maybe 25 - 30' run of feedline from the tuner to the feed point. Pretty much will be a straight shot up to the antenna. So I wasn't sure what the gain of such a short run of 450 would be plus it not being at least 1/4 wavelength at the fundamental would cause possible problems?

I don't think you will have any problems. I am sure the 239 will be able
to cope with whatever impedance it sees. If, on some particular frequency
it seems to be having trouble ... and that frequency is important to you
.... you can always add some extra 450 ohm line to make the 239 more
comfortable. The feed line losses with that length of line will be negligible.

Dr.Ace
As a novice I'm intriqued by your comments re using a pair of matched coax lines in place of twin lead to the tuner.
You have made it clear that this option will work well at the fundamental frequency, but what happens when twin coax feedlines are used with an auto tuner on other frequencies?
Should it be expected to act like regular old balanced line on other bands as well?
thanks Terry

Hello Terry,
I know I wasn't very clear. And being tired I might have mis-spoke.
If you use two pieces of 50 ohm coax then you have a near perfect match to a full wave loop antenna at the fundamental frequency.

But, As with most balanced feedlines even if there is a high VSWR on the feedline the losses will still be much lower than if you were using a single coax feedline.
The short answer is it should be expected to act like regular old balanced line on other bands as well.
73, Ace
P.S. Anyone is welcome to add their 2 cents.

I want to clarify my previous posting(s).

If you take two identical pieces of equal lengths of coax, lay them side by side and solder the shields together at both ends. Then use the two center conductors as though they were twin lead or ladder line. This raises the impedance value of the line to exactly double its original value.

If you use two pieces of 50 ohm coax then you have a near perfect match to a full wave loop antenna at the fundamental frequency! If you move up to harmonic frequencies, then this near perfect match no longer applies. Since the 100 – 104 ohms of the coax is only a near perfect match to a full wave loop antenna at the design (lowest usable) frequency.

But, As with most balanced feed lines even if there is a high VSWR on the feed line the losses will still be much lower than if you were using a single coax feed line.

And, unlike ladder line your shielded coax is impervious to nearby metal objects such as gutters, aluminum siding etc.

You still need a tuner between your 50 Ohm transmitter and your "dual coax shielded twin lead" feed line for multi-band operation.

Ace

My comments follow.

First, it won't behave exactly "like regular old balanced line" on ANY band, even the fundamental, because "regular old balanced line" is usually 300, 450, or 600 ohms characteristic impedance, and this combination is only 100 ohms (if you use pairs of 50 ohm coax). That can be an advantage to you or a disadvantage, depending on what's on the other end.

Second, it indeed really works like a balanced line, because it IS a balanced line. Even better: it is a shielded balanced line.

Third, there are minor differences between this balanced line and a ladderline suspended in space, which may or may not affect you.

One is that its common-mode characteristic impedance is much lower than that of ladderline, in case that matters. (It might not. If you have a well balanced system, this won't make a bit of difference.)

Another is that it is subject to the typical losses of coax as opposed to ladderline.

There is no fundamental reason why coax would be more lossy than ladderline, but it often is, because ladderline uses mainly air as dielectric whereas coax typically uses a plastic or foam or polymer material. So in dry weather, ladderline's losses may be smaller. But loss depends on the VSWR actually on the line; i.e., how well the characteristic impedance of the line matches the feedpoint impedance of the antenna. (Your auto tuner doesn't help this, unless you mount it remotely at the far end of the feedline.)

Compared to a single coax, the dual-coax approach would have a little better (lower) loss IF the antenna's feedpoint impedance goes high, because the amount of impedance mismatch would be less. Other than that, the dual-coax approach has exactly the same loss as a single coax.

The coax pair is a good way to bring balanced feedline through a wall into your house without unbalancing the line. If the length of the coax pair is short compared to a wavelength, the mismatch between it (100 ohms) and your open feedline (300-600 ohms) shouldn't matter, and the losses shouldn't matter either.

Andy

Andy,
Thank you for your input.
You say
"First, it won't behave exactly "like regular old balanced line" on ANY
band, even the fundamental, because "regular old balanced line" is usually
300, 450, or 600 ohms characteristic impedance, and this combination is only
100 ohms (if you use pairs of 50 ohm coax)."

The KEY word is usually.....

BTW - I have seen 75 ohm balanced line.

Also for newcomers......The higher the feed lines characteristic impedance
is USUALLY the better.

Very 73, Ace

P.S.
Any constructive input is good input and always welcome.

Quite true!

Designers can make feedlines have lower impedances, by substituting a solid dielectric material for the air (or using material with a yet higher dielectric constant), or by moving the wires closer together. The lower impedances, also often used for things like computer network busses, are done this way.

> Also for newcomers......The higher the feed lines characteristic impedance is USUALLY the better.

That's true, because the higher characteristic impedance requires using mostly air between the wires, and air has superior electrical characteristics, especially lower loss. The downside is it takes up a bit more space, and you need to be careful what gets close to it. You could also get those higher impedances by using very skinny wires, but then they have more resistance (more loss), and would be more likely to break.

Andy

Hi,

Back in the 60's .... and maybe later .... most of the cable companies carried 75 ohm balanced cable. Amateur suppliers advertised and carried the product as they now do with 450 ohm line, coax, etc.... It came in 2 forms ... the low power and high power (called killowatt version) designed to specifically carry HF RF. It was used basically the same way you use coax. .... that is for feeding resonant dipoles and loops .... and not for multi-band high SWR situations. As far as I can determine it has been dropped for the radio market ... there may well be 75 ohm balanced line made for and marketed in other services with specifications designed for those services.

Hi All,
A few years ago, maybe 10 or less. Van Gordon Engineering offered 100 Ohm balanced transmission line thru HRO and other retail outlets. Or I think you could also order it direct from Van Gordon Engineering. I called them at the time and was told it was not for QRO hign power operations. I just looked at HRO online and didn't see it listed. 73, Ace

If my recollection is right, 93 ohm twinax (shielded pair) was a somewhat popular cable type, going way back. I think its use originalted with instrumentation and "video", according to what I read. It is possible that this configuration has survived longer than the 75 ohm variety. But my guess is that it might not have come in the high power variety, since neither instrumentation nor video signals are particularly high power.

Hi,

The 'killowatt' version of 75 ohm balanced line was almost as wide as standard TV twinlead, twice a thick, and flat. the colour was brown and not quite as flexible as standard TV twinlead. The lower power version was almost round and quite small in diameter and flexible. It could be wound easily and ideal for portable operation. I have never used it. I have used the killowatt variety ..... feeding a 20m quad. antenna. A few years ago I did an extensive search for it without any luck.

3435. Feedpoint switch

Yahoo group: SkyWires
Date: 2009-04-03 21:43:37 UTC
From: Aaron
Topic: 3435 Message: 3435

Ok, I am still goofing around with the idea of making a remote feed point switch for my loop to feed it in 3 different places. SO I have drafted up a crude schematic/diagram of a what i am trying to get out of my head right now.

I want to be able to use the 450 to either feed RF or DC to the relay out at the splice points on the loop. That would in theory either open it up as a feed point or close the connection when DC is applied to the far point relay.

This one is for the default feed point which should work as a feed point with no DC applied to relay circuit, this would be opposite to the remaining feed points not yet illustrated.

Now... in this illustration, I think I am going to run into a issue with the opening and closing of the loop circuit. I am not sure if I feed past the short what is going to happen... might have to put another relay into this mess to do what i want.

Anyways throwing it out there to brainstorm on.

Ok, I got it figured out now at the antenna side. This should work with no DC applied as the default feed point. When DC is applied through the twin lead it will close the loop circuit and allow me to feed another point on the loop.

Anyone got any ideas on what relays might work best for this idea? They need to be small and handle about 200W PEP I guess since this portion will be hanging way up in the air. Might have to find some lighter weight tubing other than pvc too.

you will need capacitors inthe feedingline
or you will short circuit your relais-voltage in your tuner or trx
and after the relais not to short circuit the relais voltage with your loop antenna
just my 2 cents

Topic: 3435 Message: 3438

There won't be any DC in the circuit, the feed line will either act as transmission line or DC supply and switched accordingly at the remote switch. The remote switch... I am still drafting that up as I was trying to figure it all out on 1 sheet, the first diagram posted isn't going to be right. Now I am segmenting it all out so I don't get myself corn-fused.

Once I get the remote switch logic figured out the only things will be figuring out the appropriate relays and then to figure out how to decouple or choke the RF from going into relay coils at the loop switch.

I think this may work... not sure how much of a difference the radiation patterns will change but sounds like a fun project to experiment with.

Hi Aaron,

Lets hold the concept to a single feed point and describe what is going to happen. If you can get one feed point to work you can add additional circuits at other feed points.

1. You want to have a relay at the feed point that will short the feed point when the relay is NOT energized. When you energize the relay it will open and remove the short and attach the feed line to the feed point. You will need a 2 pole 2 position relay to accomplish this task. You would make a number of these at different points in the loop to test their effectiveness.

2. You want the feed line to carry the DC for switching the relay and to carry the RF when the feed point is open and connected.

First, it is not unusual to accomplish the second point ... that is carry RF and Dc on the same cable. The method used is to use isolation chokes and capacitors to separate RF from DC circuits and vice versa . This is best done when the feed line is low impedance .... eg with coax cable. You mention 450 ohm line ... which will present various complex impedances ....

which make designing an effective RF/DC isolation system difficult. The system could be designed if careful attention is paid to system resonance. All band operation would be out of the question.

If the loop is to tested this way on one band then you might consider using stub feeders at the various feed points of interest. The relay switching could be done at the ends of the stubs ... closer to the ground where you could easily run separate DC lines to the relays and avoid using a single line for RF and DC. However, whether you use 450 ohm line or coax ... you would be limited to one resonant frequency as you would have to cut the stubs to this frequency.

Good point. The cable does not have to carry DC and RF at the same time. However this raises 2 additional problems. The feed point is normally open and the relay coil is connected across it, a problem when feeding RF. Second, you cant feed DC on the feed line as the feed point is a DC short (wire loop). So, either way ..... normally open feed point .... or normally closed feed point .... you are going to need both capacitors and inductors to allow one cable to feed DC or RF whether they are on at the same time or not.

This then leads to the points I made on my previous post ... you need to keep the point of RF and DC separation at a low impedance.

i think the best way is to make a dc cable and a ladderline to each feedingpoint
if he uses the loop only for the fundamental frequency switching feedingpoint will gain nothing
changing the feedingpoints will give different patterns only on the higher bands where the loop is NOT a cloudburner

Here is the latest diagram, switching logic is now figured out:
http://groups.yahoo.com/group/SkyWires/photos/album/836998787/pic/1990466535/view?picmode=original&mode=tn&order=ordinal&start=1&dir=asc

If you scroll down to the bottom of the diagram you can follow it up the circuit. RL1 & RL2 are the first tier of switches and solely route RF to the next tier.
The second tier (RLA, RLB, & RLC) determine the function of what will be sent to the loop switch located at the wire. Off is RF and ON is DC feeding up to the wire which will keep the loop circuit closed at that point.

Now the only thing left is the RF chokes that need to go between Pins 1&3 and 6&8 on RL*1 at the loop switch to prevent RF current going into the relay coils when that switch is acting as the feed point.

I think this will work now, lots of relays but I don't see any way around it. ...and yes this concept is to make the patterns change at higher frequencies. Since the antenna seems to out perform any other antenna I have ever put up 80 - 10 I can't see the reason why not to do this and make the antenna just a little more dynamic.

I would and try to model this but I can't find any modeling program that will work correctly with Vista 64 and I have been too busy to set up a VM just to do antenna modeling.

Hi you all, greetings from sunny Brazil, here is PU1BZZ Alexandre :o)

I've heard about this incredible skywire antenna and I'm willing to make one here next weekend, using ladderline to feed it. So I'm here for some advice.

My terrain is a 12 x 33 rectangular-shaped with a house in the middle, so I can feed the antenna in the middle of one of the biggest sides of the rectangle. But I know no one who has made an antenna like this. So, here are a buttload of questions:

- Can I make it rectangular, so it can be used on 80mtrs?
- The highest I think I can put it is some 6mtrs (about 20 feet). Is it too low?
- I'm planning to use #14 wire to make a ladder line. What is the best distance between wires to keep it at a reasonable impedance (300 ohms? 450 ohms? 600 ohms?)? Or is better to feed it with RG213 coax?
- Can I use the same #14 wire for the antenna?
- Does it matter the place I feed it? I can build a relay system to change the feedpoint, but is it worth it?
- Does it matter the polarity of the feeding if I use coaxial? Is it worth to put a latching relay to change the polarity of the feed?
- As a newbie, any tip I should have? :o)

Thanks you all!
Alexandre, PU1BZZ

Well since I have been experimenting some I'll relay some of my findings. I have not really noticed a difference since I switched from direct feed with coax to 450 ladder line for the exception it looks to be a little longer now on 160. Think the ladder line shifted my resonant freq down some.

I have since moved my tuner (SGC-239) from the shack out near the loop. It is about 30 feet below the feed point and mounted on a dish mount on the side of the barn. Running RG8 from the shack to the tuner and 450 from the tuner to the loop. I may actually mount the tuner in the tree later this year and feed the loop directly into the tuner just to see what happens.

As for your lot size looks like it's about 294 feet which puts you about 3.4 mhz.. looks close enough if you're running a tuner and you plan on using on other bands other than 80.

The feed point switch idea I came up with may or may not be worth it. I have yet to try and build it yet but in theory it should alter lobes patterns on higher bands. My antenna is working so good the way it is I am not sure it's worth the effort other than to experiment and satisfy my own curiosity. Considering your loop would be square I am not sure that switching the polarity of the feed would show any difference. You may see something by doing that if you feed it off center but you would have to model it to see.

About the best tip I can give you is the SGC-239 tuner + as much wire as you can get up = one fun antenna. I have burnt myself out on antenna theory & design and was surprised the above formula has been the best multi band wire antenna I have used to date. I think most will concur, just put up the loop the best you can and be very surprised. Get it up and tinker later.

--- In SkyWires@yahoogroups.com, "Alexandre Souza" <alexandre-
In my setup,I use about 400 ft of 14 ga wire. It is somewhat a rectangle. I feed it in the closest corner near the shack with 450 ohm ladderline. The height varies from 55 ft to about 30 ft. I bring the ladder line to the wall outside of the shack where it connects to a 4 to 1 balun then about 12 ft of rg8x to the tuner. It work on all band 160 thru 6 meters. 160 is mostly local stuff but the rest of the bands I've work dx on. So, put up as much wire as possible and get it high as possible and you'll be pleased with its performance. For a article on construction of one goto:http://www.n4kc.com/ Don does and great job on his construction article..73, Alan
ps: his and my antenna are very similar

Bill, I use almost the same setup as your considering. Its not quite large enough to be resonant on 160 but the autotuner in the rig brings it right in. Its tied off at 4 different trees so its not a square and has one long leg. It is fed at the sw corner nearest the shack. I run maybe 50 ft of ladderline to a 4 to 1 balun and there into the shack where it goes into a manual tuner for when i use the amp or direct to the rig where the autotuner takes care of most freqs. It works from 160-6 meters. 160 is mostly close in stuff maybe out to 400 miles. On the other bands I have worked and do work dx. Sometimes the signal is as loud as my hexbeam and other times not. The height of the loop also varies in height from 30 to 55 ft. good luck, you love it...73, Alan

if you have the room for a fullsized loop for topband ... go for it ... i have a setup like you .. a loop for topband fed via ladderline with a balun and a tuner ....
i have 2 different lenght of feedind line
about 18m from loop to shack and another run of about 20m that i switch in for some bands
the reason is with this setup i can switch my tuner OFF .... so no tuner losses :-)
and on the bands where the swr is not 1:1 it is so low (>3) that i can use the tuner in the rig or the pi section of the pa .... so you need no tuner most of the time
look for (loop.xls) in the filearea of this group
it is an excelsheet what i made for my notes of resonance points and swr
if you wanna try out this setup write to me offline to callsign (at) freenet (dot) de

Thanks Sigi, and also to Alan. I hope it won't be too long before we take possession. One thing I'm wondering about, modifying a tuner so that the balun is on the rig side, and that being a 1:1. Bringing the balanced line right in to the tuner. To minimize loss in the balun by having only converting 50ohm balanced to 50ohm unbalanced. Have you, or anyone else tried that? And did it make enough of a difference to notice? If it's only a marginal improvement, I might not bother with it.

Thanks again!

3456. RF getting into speakers

Yahoo group: SkyWires
Date: 2009-05-15 15:26:25 UTC
From: Mike
Topic: 3456 Message: 3456

I normally use either of two IC-756 Pro-II radios at two locations in my home. Both use the Icom AH-4 auto-antenna tuner. Both feed similar 160 Meter loop antennas, fed with 450 Ohm window (ladder) line. (No balun is used; I simply attach the twin-lead feedline to the HOT and GROUND sides.)

I have a new unit, a Flex-3000 radio. The built-in ATU (auto antenna tuner) is very limited, so I must use an external ATU (tuner) to achieve a match.

I have two two external tuners to try:
A. MFJ-993 ATU, which has both COAX and a BALANCED output as choices.
B. LDG AT-100Pro, which has COAX outputs. (No balun built in)

My Flex-Radio appears to have a good enough transmitted signal, per the reports I get, compared to the (to me, GOLDEN) reports that I get if I use the Icom radio on this same antenna. (The other Icom setup is upstairs; It has a similar signal, when comparing.)

My point is that the Flex is doing well, as far as receive and transmit signals.

BUT: I have varying degrees of RF getting into whatever speaker that I use. The degree differs from band to band. (20 Meters causes the greatest amount of "muffled sounds" as I transmit in SSB mode.)

I have tried a ground at the Flex-Radio, and at the tuner.

I have NOT lifted the ground at the radio, as a trial!

I have moved the tuner from on top of the Flex-Radio to a point that is ten or twelve feet removed from the Flex-Radio, so that it is at the same point or area as the 450 Ohm feed-line actually ENDS. (This is achieved by cobbling together three pieces of RG-58 coax, with UHF barrels to join the too-short coax length's PL-259 connectors.)

I have tried both a 4:1 and a 1:1 current balun; The 1:1 is noticeably EASIER FOR THE ATU TO TUNE, but no great difference is seen between the two as far as the RF-in-the-speakers problem.

I do have a home-made "RF choke" that I built some time back; It is about 10 to 15 turns of RG-213 coax wound on a 5 inch PVC tube. It is fed with an SO-239, and was preciously attached to a 450 Ohm twin-lead fed antenna. I HAVE NOT TRIED this choke,

yet

My ground system is far from OK or correct: The radio is on a bench at an inner wall of my basement. The ground wire has to be routed UP, then OVER (to the LEFT) to the outer wall of the basement shop, then to the ground.

The ground situation appears to be able to "control" the degree of my speaker-barking the most. (All is OK and clean, if I use a dummy load, of course.)

So far, the MFJ-993, employing the unit's built-in Balun, is the cleanest, by a noticeable amount!

I have not tapped into the house-wiring's ground; This was suggested bu one fellow. (This would mean about a 15 foot run of wire to the breaker-box area bu going UP, then to the RIGHT-FORWARD to reach the power panels.)

I am looking for some hints or ideas, please.

Thank you!!! -Mike- KOJTA

try the mfj and put your chokebalun between the tuner and the rig
do not ground tuner but ground the rig .... that is what i would try first ....
surely you made a choke for the atu power lines didn´t you ?
put chokes over EVERY cable that goes in or out of the flexnet
if you are using amplified speakers try a different set (some are better not getting rf in)
also try a headphone instead the amplified speakers
put chokes over the power cord of the speakers
use a different power outlet for the speakers / the radio / both
etc
etc
etc
just my 2 cents

Hello!! Great ideas!!! (Thank you!)

The home-made coax-on-a-PVC-tube has coax input only (This is the SO-239 I had mentioned.) It has no OUTPUT to a coax. I had used this to feed the twin-lead (450 Ohm window/ladder line), you see.

I have noted that the three different line-in speakers that I have ARE very different as to RF suseptability. (-If this is a correct term.)

I had tried to run the system with a ground on the radio ONLY, but this was no better. (I cannot even recall if it was BETTER or WORSE...)

I have NOT tried to run the system with a ground at the TUNER only; I will try this next.

I have one of them powered by a 12-volt power brick, and one is powered bu a USB connection. (The Altec-Lansing one is the BEST, and is AC-powered; The power supply is built into the bass-woofer speaker box.)

I had not tried the ferrite cores (chokes) on the leads, but I will!

I could also see if I can just run the speaker with a battery.

I had not tried using the radio with a headset. (Brilliant idea!)
Thank you for this one; I should have thought of this, but was

too focused on the speaker applications.

Thank you!!!

UPDATE:
I have tried a LOT more setups, re-arranging the grounds, adding,
deleting, etc.
I have worked toward MINIMIZING the offending noise in the speakers
if I am on SSB or on CW.

I have reached an almost acceptable point...

- I have the LDG AT-100Pro ATU on top of the Flex-3000 radio.
- Adding the ground at the ATU makes no noticable difference.
- The radio IS grounded at this point.
- If I ground one side of the twin-lead that feeds the loop, I
can make a further reduction of the noise.

The Altec-Lansing sub-woofer speaker is the best, so far, but
it still has noise when I transmit.

If I disconnect the external speaker system, I have no noise.
(If I use the HEADSET, I have no noise, as I recall.)

I have added several ferrite chokes on various points; NO HELP.

I have not tried to simply re-arrange the sub-woofer speaker system.
I have not tried to add a ferrite choke on the AC power lead to the
Altec-Lansing speaker system.

I think I will open the speaker system up, and add RF bypassing to
as many points as I can see that would be logical. (At this point,
I am assigning the troubles to my high SWR causing some small bit
of RF to be in the vicinity of the radio, which the speakers that
I have been using, are all sensitive to.

Thanks for the input, so far!!

Topic: 3456 Message: 3460

A few thoughts. Take these with a grain of salt as my practical experience is somewhat limited; a lot of this is more theory than practice.

Does the amp need to be turned on, and does it depend on the volume setting? This could tell you if the RF is getting into the amp itself, the inputs to the amp, the speakers, or the speaker cables. Often RF appears on the speaker wires acting as receiving antennas, then gets rectified by the amp and turned into sound. This type of RFI may be heard even with the amp turned off.

If they are computer speakers, almost all of them are known for being susceptible to RFI, because they are cheap and poorly designed.

In other words, there might be nothing wrong with your ham setup, but the speaker is at fault, and you can't do anything to the rig or antenna to make it better, short of shutting it off or going QRP. In that case, focus on adding toroids, chokes, capacitors, etc. to the speakers/amp.

> My ground system is far from OK or correct:

I wouldn't worry too much about your ground system, and would NOT suggest trying ways to augment it in an attempt to fix your RFI. With your antenna you don't actually need any ground (except for safety!). A loop antenna is self contained and needs no ground. As long as you feed it properly, there should never be any RF current from your rig into ground. (Now if you were feeding a tower, that would be a different story.)

The feed to the loop should be balanced. When you feed it unbalanced (one side grounded), you are forcing an unbalanced signal onto your ladderline, which makes it an antenna too, and that's not good. Then the return current IS through ground, and that's not what you want. Feed it either from a balun, or a balanced tuner.

Putting the balun between the rig and tuner might be OK as long as you realize this makes the tuner "hot" so you need to isolate it from everything else. Not necessarily hot enough to bite you (though it might), but you want to make sure it can't touch anything else and has minimum coupling to it. You will detune it by touching it. And powering an isolated auto-tuner becomes a problem.

Your station grounds might matter if there is RF current going through them. And ideally there shouldn't be any. As long as there is RF current, you cannot eliminate its effects, you can only reduce them, and 'diminishing returns' quickly comes into play. A ground wire of any length is no longer ground. So focus on eliminating RF ground currents rather than beefing up your grounds in an attempt to reduce their effects.

> I have not tapped into the house-wiring's ground;

Good. Don't. (Except for the usual 3rd pin safety ground.)

> This was
> suggested bu one fellow. (This would mean about a 15 foot
> run of wire to the breaker-box area bu going UP, then to the
> RIGHT-FORWARD to reach the power panels.)

The problem is, if there is an electrical fault, bad things can happen. After your house burns down, your insurance company might deny payment claiming it was your fault.

If you get your RF cleaned up by feeding your balanced antenna with a balanced feed, you may find that you still get RFI. Then you can focus on adding remedies to the affected components. The best place to start, is with any "antenna" that goes into the audio system.

If all else fails, you may even need to think about moving the loop antenna. By definition you are creating a strong RF field, and if your speakers are susceptible to it, your only choice might be to make that RF field not as strong where the speakers are. But if you've got RF ground currents, some of your RF field isn't coming from the antenna, it's coming from your ground wires.

Regards,
Andy

Hi Bill,

I assume you mean connecting the balanced feed line directly to an unbalanced tuner and placing the 1:1 balun on the input side.

Yes, it is certainly possible to do. Yes, I have done it. Yes, it makes a difference. It is not all that difficult to do. It can be accomplished with no actual modification to the tuner other than to take steps to isolate the frame, including the coax input from ground.

One side of the balanced feed line connects to the output of the tuner and the other side of the balanced feed line connects to (ground), the tuner frame. The coax from the radio connects to the input of a 1:1 balun .... one side of the output of the balun connects to the center connector of the coax input of the tuner and the other side of the balun output connects to the tuner ground (frame).

Critics say this arrangement is not a "true" balanced antenna tuner .... whatever that means .... as long as antenna currents are in balance I am satisfied ... and this arrangement will achieve that end. The only problem is that the typical unbalanced antenna tuner may not have sufficient tuning range. this can be accommodated by inserting and removing (as the case may be) lengths of feed line to make up for any shortcoming in this regard.

I presently use this system with an SGC automatic antenna tuner SGC-239 located at the base of the tower ... (inside the basement window). I feed the tuner with coax via a 1:1 balun the output connects to 450 ohm line as outlined above. You need to take care to keep the tuner frame isolated from common ground. The antenna at the top of the tower is a loaded dipole arrangement that covers 40-10m very nicely.

Bill, I tried using direct feed to a Johnson Matchbox then to the rig vs the current setup. I could not tell any difference on transmit signal or receive signal. There might have been some difference but I could not tell it.So, I went with 4 to 1 balun because it was a lot easier to get through the wall to the shack. 73, Alan

Hi Mike,

See my previous post. I have a similar antenna arrangement in that I have an ATU that normally connects to an unbalanced output. I also connect 450 ohm line in the same manner you have outlined ... e.g. one side to the hot connector and the other side to the tuner frame (ground). The difference is I isolate the tuner from RF ground at the input connector by using a 1:1 balun.

The balanced line comes in at the basement window and connects to the tuner at that point .... the operating position is at the other end of the basement (about 35 ft.) coax joins the radio to the tuner. The arrangement maintains RF balance on the 450 ohm line and removes RF from the outside of the coax feed line. I use a SGC-239 tuner ... similar type to your AH-4. I also tried the other arrangement ... as you mentioned ... e.g. putting the balun between the 450 ohm line and the tuner ... with much less success. The only care is to be sure the tuner frame stays isolated from any common ground.

I am sure if you used this system you would avoid your rf problem.

PS I also used a Flexradio SDR-1000 with this arrangement with no RF problems.

Good day, and THANK YOU for your comment. Your first point brings up a new point of attack, maybe:

In my case, I get the almost static-line (HEAVY static sounds) on some bands if I have the powered speakers turned ON, but only allow the SHIELD of the input stereo plug to contact a ground on the Flex-Radio, and then transmit in SSB.

I mention this, as it is different from your fist paragraph's points/queries.

Yes, the speaker must be turned ON, I BELIEVE. (Almost sure.)

I DO NOT think the powered speaker's VOLUME CONTROL has an effect.

I have opened up the speaker system's base unit, preparing to add some bypass caps, so it is not functional at the moment. -So, I cannot tell you with absolute certainty.

>
> If they are computer speakers, almost all of them are known for being
> susceptible to RFI, because they are cheap and poorly designed.

Yes, these are speakers that are intended to be fed by a computer. The base unit is heavy at 6 to 7 pounds, and is a unit that houses the 110 VAC power supply as well as the amplifier and the large bass speaker.

I'd tend to agree, but I have an IC-756 Pro-II at the same location in my basement shop. It feeds the same antenna, via an AH-4 auto-antenna tuner. No troubles.

You are highly correct on the loop NOT having a need for a ground. However, in my case, I am "providing" a ground, as the ATU is being fed by a coax cable from the Icom radio; The ATU is -intended- to be feeding a long-wire antenna. But in my case (and I have done this with several installations; This is one of three that I NOW HAVE IN SERVICE, and all have the twin-lead (window-line) wires attached to the HOT side of the AH-4 ATU, and the GROUND POST of the ATU.

This does not make it right; It is just the way I am doing it. I have seen and read of many others with the same configuration, so it is almost an acceptable method.

Again, if I use the Icom radio and AH-4 ATU, I have no to EXTREMELY LITTLE RF getting into the powered speakers...

So here, the ground is my FRIEND!!

I had also found that if I try to duplicate this grounded side "design" that I now use with the AH-4 ATU units, I get a significant decrease in the RFI to the speakers. My transmitted signal does not suffer, so I feel no allegiance to adhering to my NOT grounding a leg of the twin-lead antenna feed line.

VERY interesting point!!!!!!!!!

I say this, as I had attached the MFJ-993 ATU to the loop's feed-line; I felt that the RF that was floating about was reduced, but this was too far back to recall exactly. But, you make a good point!!!

My baluns are both set up with an SO-239 input and have wires as the outputs. They are both intended to feed a dipole, etc, and act as the center insulator.

So, I cannot put it in series, locating it between the radio and the ATU, I am afraid.

Yes, I agree...

If I add or remove a ground, the "pattern" or degree of RF into the speaker system shows a change.

I think I have the RFI with any/all of my tuners.

This is why I am considering attacking the design of the speaker.

I am thinking of the possibility of adding an isolation RESISTOR in the shield, or ground return of the input to the powered speaker.

I mention this, as the dramatic HEAVT crackle that I hear if I have only the shield or ground of the input lead of the powered speakers touching a ground on the tuner or the radio!!

>
> Regards,
> Andy
>

Yep; I agree, Andy. I have a strong field. The shield-to-grounding crackle is the interesting point... This CRACKLE is so very loud and very dramatic ON SOME BANDS, such as on 17 Meters, in my case..! Other bands, it is OK to non-existent.

Thank you VERY MUCH; You have given me a LOT to try. I hope that I have answered your points. More importantly, I hope that my earliest statements on the shield-to-ground as the only need to produce the RFI will give you the AHAA! factor.

OK; I do NOT have one of these units.
My two baluns (a 1:1 and a 4:1) both have an SO-239 as the input; The outputs are simply wires, intended to attach to a dipole, etc.

Now, I do have this home-made "RF Choke" doo-dad that I had made up some time back; It has an SO-239 at the input, and the RG-8 coax was set up with the shield and the center as the two connections that would feed the twin-lead of the loop antenna. maybe I could cobble a second SO-239 there, and see if this would offer an IMPROVEMENT!!!

OK, except for the fact that (in my case) I was unable to add either of my baluns to the "input" of the tuner. I added the baluns at the output of my LDG AT-100Pro ATU. The LDG tuners have SO-239 connectors as the input and output.

But, yes: in the case where you were duplicating my AH-4 ATU-to-Icom setup: This is the same. But... In this case, I have no to very little RFI!!!

I only have the RFI issue when I run the Flex-3000, feeding an LDG AT-100Pro tuner, with the SO-239 output, Here, I felt the need to add the 1:1 balun.

U used to have an SDR-1000, also; In this case, I used the SDR-1000's built in ATU. I could feed it through a balun or I could simply attach the window-line to the BNC connector at the RF output port of the '1000. It ran fine. I had no RFI. (Go figger...)

dear mike
what about af-transformers between your rig setup and your amplified speakers ....
what helps from getting no ground loops on transmitting and receiving via a souncard could probably help with your rfi problem ....
speakers and trx setup/pc are now isolated with different grounds and/or floating ground ....
that is on the speaker side .....
putting your 1:4 on the OUPUT side of your tuner is the other thing to try ....
output can be atached to ladderline so that is no problem .... for the input i would take a short lenght of coax wit one plug and would put the plug to the balun input
now strip off a lenght of the isolation to connect this to your atu.... if this works okay you can build a homebrewed 1:4 and put it there
let the other balun there
or put a homebrewed balun IN the atu with a jumper wire outside if there is room in your atu
good luck

That is exactly my situation .... my 1:1 balun has a coax input and 2 terminals (wires) at the output. One balun output wire goes to tuner ground and the other goes to the center pin on the coax input !!!! simple .... the distance between the 1:1 balun and the tuner is about 3 inches.

In the case of the SGC tuner there is no coax input connector .... just direct connections to the circuit board. I have used the system with both types of tuners ... those with a coax input connector and those without.

Putting the balun between the tuner and the radio (next to the tuner) is easily accomplished regardless of the kind of connectors on the tuner. After all, a coax connector is a 2 point connector (ground frame and center pin to the unbalanced tuner circuit). the only amputation necessary is if the tuner input uses a feed thru coax. Most of the SGC auto tuners come with a length of coax at the input. If you have an actual coax connector at the input and output of the tuner the problem is easily solved with 2 short (few inches) lengths of coax with a male connector on one end and shield and center conductor exposed at the other. Then you don't have to do perform any mod to the tuner. The shield and center conductor simply connect to the balun output. At the other side of the tuner the shield and center conductor would connect to the parallel feed line. Be sure to keep the frame of the tuner above ground .... and voila

you have a reasonable facsimile of a balanced antenna tuner .... and no RF on the coax to the radio.

I have tried several types of 1:1 baluns: 1- simple coax wound in a coil (moderately effective and bulky) 2. parallel wires wound on a ferrite core (much more effective and less bulky 3. a pair of air wound bifiler coils hooked up as a 1:1 transmission line transformer (also bulky ... but the best performance). This arrangement (balun on the radio side of the tuner is far superior to the opposite arrangement. Stable, predictable, and NO RF coming into the shack.

OK!!! This sounds the most promising!!! Thank you VERY much for the detailed explanation. In my case, the LDG tuner has SO-239 connectors at the input as well as the output, so I am going to duplicate your efforts. It seems that I'll be able to do this with ease.

Oooops... This might be a "gotcha, as my ATU units (Auto-antenna tuners) are in need of DC power. So, I'll not be able to do as you had said, "Be sure to keep the frame of the tuner above ground" I'm afraid. (The power-brick is sort of tied back to the AC mains...) If this is a factor, I will see if I can TUNE, then disconnect the ATU... As an experiment, if nothing else. If I do need to drop the power brick, maybe I can do a battery-operated setup.

Excellent info, Jim!! (Thank you, AGAIN!) I will try the home-made single winding choke that I made up from a length of RG-8 coax. If this does indeed give me a good result, I will have to see if I can duplicate the "better" designs that you have mentioned.

Yes, in my case, I had the Balun on the "wrong side" of the tuner! (Very interesting!!!)

Your mention of "parallel wires wound on a ferrite core" is puzzling: Is the "parallel wires" to be two runs of RG-8 coax? -Or a run of (what length) 450 Ohm twin-lead..?

The same goes for your description of "a pair of air wound bifiler coils" applies. (Very interesting, but still a puzzle. Is this stuff going to be found in my ARRL handbook? -Or in my wire-type-antenna book by ARRL?)

I just got home from helping a friend erect two towers, so I am BEAT. But I will try to get at this as soon as I can.

YES!! I had considered this at first, but I have no isolation transformers available at this time.

Yours is an excellent idea!!!

I had also considered a "rubber" connection to the return or ground side of the stereo input connector-cable: In this, I was thinking of adding CARBON RESISTORS in the connections, thinking that this might drop the effect that I now see, if I simply touch the shield of the plug)from the speaker) to any frame-ground on the radio or on the LDG tuner. (As it now is, I get a very DRAMATIC noise (crackle, etc.) if I transmit on SSB on 17 Meters, if just the shield or common connector is touching ground on the radio.)

In the case of my adding return-resistors, I was hoping that the heavy SOUNDING signal would be largely absorbed by the resistor, yet, I'd have enough of the desired audio to work for me.

As for placing the Baluns on the OUTPUT SIDE OF THE TUNER, this is what I had been doing. This was not doing the trick for me. This was also "voted down" by another fellow (Jim) whose comments I just answered. So... I have done this, and I must say that it most likely did some good, but it did not resolve the issue. (I tried both a 1:1 and a 4:1 Balun; The 1:1 seems to be the best.)

Thank you VERY MUCH for your helpful comments!!!!

I forgot to mention .... with my SGC 239 auto tuner I also use a bifiler wound RF choke for the power line. At the moment I use a ferrite doughnut (about 2" in diameter) .... comes from an old TV set. I wound a pair of insulated wires (approx 16 guage) - and + 12 vdc. about 12 turns to form an RF choke. It can also be wound on a ferrite rod to form a choke.

Andy;

A short re-cap for you, with some more observations and answers to your queries:

The amp DOES NEED TO BE TURNED ON for me to hear the RFI.

If the amp is not turned on (By unplugging the 115 VAC, as there is no power switch), I do not hear any noise at all. (No receiver, no CRACKLE if the BCI, etc.)

The RFI (HEAVY crackle) that I hear is independent on the volume setting of the Altec-Lansing powered subwoofer-speakers.

I hear the RFI if the speakers are attached to the Flex-3000 radio, in the normal audio-out to the speaker situation.

I hear the heavy CRACKLE if I disconnect the plug that is normally plugged into the radio's LINE OUT port, and simply TOUCH THE BARREL or the GROUND/SHIELD to a common ground point, or screw on the radio.

If I unplug the input cable from the radio, I have no RFI. (The cable is still attached to the input port of the speaker unit.)

I have added .01 uFd capacitors to bypass the 115 VAC as well as both sides of the stereo inputs on the powered speaker. This was no help at all.

If I operate the radio into an MFJ dummy load, I have no RFI

When I attach the antenna, I have varying degrees of RFI; It is worst on 20 Meters. It is present to a small degree on 75 Meters. It is OK to non-existent on all other bands.

What is all of this telling you?

Thank you!!! -Mike- KOJTA

dear mike
i think that resistor would not help
ground loop problems can NOT be solved with resistors
resistors are the reason for potetial differences
potetial differences are the reason for hum noise etc....
so audio transformers surely would help ..... look in your junk box ... or in your old computer "waiste" :-)
got an old modemcard ... telephone modem ... telephone answering machine????
there you can find transformers ....
if you have the problems only on 1 or 2 bands try a different lenght of ladder line
maybe with your setup you have on 17 a high voltage point on your lower side of the ladder line
try to lenghten or shorten it a bit ... now you are on a current point and your balun would work better
maybe THAT solves your problem

Your logic is CORRECT.

I chose to try resistors, as I would have the severe CRACKLE in the Altec-Lansing powered speakers if I had the SHIELD touching a ground-point on the Flex-3000 radio.

I have two cables that I use with a SOFTROCK (RXTXv6.3) radio; These cables have mini-stereo plugs on one end, and a female header-connector on the other end(s).

I first added 2.7 K resistors to the ground, then to all three leads. (I had the resistors plugged into each of the felaye connectors, which effectively duplicated the cable that was now in use to couple the Flex radio to the powered speakers.) The RFI has decreased a lot.

I went to 10K Ohm resistors as an experiment; The RFI noise dropped a LOT more.

But, as one would expect, the receiver's audio dropped more.

All in all, I have dropped the offending hash (the crackle-pop I hear if I transmit) my 95 percent. The audio level is Ok, as I still have more than enough.

BUT: I am simply MASKING the problem! It is not a cure!

> so audio transformers surely would help ..... look in your junk box ... or in your old computer "waiste" :-)
> got an old modemcard ... telephone modem ... telephone answering machine????
> there you can find transformers ....

I will look for audio transformers!!! I had this same idea, but I was considering getting a couple of audio transformers from Radio-Shack. -I had not considered looking for an old piece of equipment that would allow me to achieve the task. (Great idea!!!)

> if you have the problems only on 1 or 2 bands try a different lenght of ladder line
> maybe with your setup you have on 17 a high voltage point on your lower side of the ladder line
> try to lenghten or shorten it a bit ... now you are on a current point and your balun would work better
> maybe THAT solves your problem

I do believe this is the BEST way to resolve the crackle-noise that this RFI-to-speaker is giving me. (The antenna is obviously the factor, as the RFI changes from band to band.)

The root cause is RF getting into the audio system, but it is only on a couple of the bands!!! So, YES; -You are correct

I can add length. It would be very hard to decrease the window (ladder) line length.

But I am not at all sure if I should apply a DEFINED LENGTH of line, of just "try" a few lengths!!

In my case, the worst offense is on 20 and 17 meters

I will also tell you that the antenna is a loop antenna, with about 80 feet of the 450 Ohm twin-lead feed line. The loop's wire is about 507 to 520 feet long.

I have two ATU units (Auto-antenna-units) that I can view. One is an MFJ-993, and the other is an Icom AH-4.

I will offer the following as a graph of what the VSWR is THROUGH EACH OF THE TWO ATU UNITS, so that the real load that is seen by the radio might closely be.

In both cases, the ATU devices will be OFF, so will be in BYPASS mode.

I have noticed that the antenna has a 1:1 SWR (unless noted as different, but a significant DIP) at the following, with the MFJ-993 in bypass:

1.925 (2.5:1)
3.92
5.6
7.8
9.5 (1.5:1)
11.4
13.4
15.1
17.1
19.1
20.1
22.5
24.6
26.5
28.4 (1.5:1)
30.0

I have noticed that the antenna has a 1:1 SWR (unless noted as different, but a significant DIP) at the following, with the Icom AH-4 in bypass:

1.6
2.6
3.97
5.6 (3:1)
7.1
8.1
9.5 (2.5:1)
11.3
12.5
13.5

15.2 (2:1)
16.8
17.8
19.8 (1.5:1)
20.8
22.8
24.8
26.4
28.7

Just to recap, my most offending RFI is on 20 and 17 Meters.

If I LENGTHEN the feed line, how much would be a LOGICAL length to consider?

Again, I do feel that the root cause of my RFI is the antenna's load. All is OK, if I transmit into a dummy load.

Thank you!!

Yep; -I agree! How much should I consider adding? (It would be almost impossible to REMOVE feed line length!)

I could also change the actual loop antenna's wire length! This would be a task, but not at all impossible.

Mike,
Did you every try switch out those speakers. I remember a while back I tried some PC speakers on my rigs, and they were Altec's as well. Needless to say regardless how so so they sounded I ran into RFI issues with them as well. I wound up ditching them because all the audio gear I have here was untouched by any RF. Since I have my DATA Out going to the PC anyway I just route that audio out to my studio monitors when using phone. I also have a 5.1 Logitech system hooked up as well, still no RFI.

Not sure if all the effort is worth trying to fix something that is most likely super prone to RFI issues to begin with.

okay your dips are not on 20 and 17 they are between this 2 bands .... make the feeder about 2 or 3m longer maybe 4 ??? ... now the 7.8 drops to around 7.2 ...3.9 drops to 3.6
11.3 drops to 10.5
15.2 drops to 14 etc .....
maybe that would help
if you have the low swr spots not on or near the hambands the tuner can tune it but with conected to a high voltage point .... on 17 and 20 your sweet spots are far away so lenghten the line and try again

I think you are correct that these units are simply PRONE to this sort of trouble. I have a USB-based speaker set, which is also "receptive" to this RFI, I must add. But if the Altec-Lansing is a poor design, so be it.
I did add .01 uFd caps across the 115 Volt AC input and across the input lines; NO HELP.
Thank you!!! -Mike- KOJTA

Great info!! Yesterday, I began this experiment, as it happens!!!

I added three scrap pieces, 7.25, 9.25 and 12.25 feet are the lengths.
With 19.5 or 21.5 feet attached (hung around my basement shop, trying to keep it away from metal), I was the happiest. (19.5 feet was the best, 21.5 was #2 and 16.5 was in third place.)

Your one estimate of 4 Meters is in this area, so you are correct!

Being that the 160 Meter loop antenna is SHORTER than the popular 540 feet, I am now going to attack this as the problem-child. It was getting late, but I did manage to make up a holder that would take up two feet per "round."

I removed the previously added twin-lead feed line from the previous experiment.

I shortened the actual antenna wire by 12, 16 and then 22 feet; It progressively got worse. By this time, it was quite dark outside, so I had to quit.

Bottom line: I must LENGTHEN the wire. It is dark outside, almost, so no more floundering about for me, today.

I do not have too much room, but I believe I can add at least 10 to 15 feet. This is maybe not enough.

I could also move the WEST pole, but this will be some effort. I could loosen the guy wires and walk it over a few feet at a time. (Repeat as needed...) If this should happen to take place, it would meet the grand plan a lot better, as this one is "in" slightly from the desired. If it were OUT, or further West, it would allow the antenna to be more perfectly square. I can see this happening!!! If I moved this pole, it would offer a bit more clearance for a tree, also.

Plus, it just might TUNE better!!! What a concept.

I will keep you posted!!!

I have MOSTLY resolved the issue of RF getting into my Altec-Lansing powered speakers by doing ALL of the following, just for all who might be interested:

1. Added a 10K resistor in series with all three wires. (Ground, left and right audio.)

2. Added a stereo ISOLATION TRANSFORMER unit to this same connection between the radio and the speaker.

3. Added a ferrite choke over the 10K resistors.

I still have a small bit of HUM, but the RF is now GONE on ALL bands!

If I reverse the 115 volt AC power plug, the hum is further reduced.

The HUM is only present if the speaker is actually connected to the radio. As-is, it is quite tolerable.

73 to all for your fine and very productive suggestions!!

Go to the home page for this group and click on 'messages' and search for spam and you will see this has be discussed to no end, we moderator do not have the authority to prevent this, but there is another group that I'm a moderator of as well, it's called LoopSkyWire. There we moderators have to approve new members, so if they don't include their Ham call or the reason they are interested in the group, there is a strong chance they won't be allowed to join. I must say the 'spam' is almost nonexistence over there. Here is the web address for the group, http://groups.yahoo.com/group/LoopSkyWire/?yguid=401597987

There is.

But the moderator is unable to control spam until after it happens.

So just use your Delete key.

So eliminate the spammers before they spam. If you take a look, all of them uses three names, without spaces. It is just a matter of deleting all names (or moderating them) that has the same pattern, and after that make all new users moderated until confirmed. Works in all lists I moderate.

Rare message?

I have 60 messages from this group (since I joined the group in
05/03/09). 21 are from "freebies", and 3 more about private photos and like.
We are talking about 1/3 of all the messages.

Sorry you all, I'm leaving. Too little talk about skywires, too much
things offtopic.

The groups you moderate probably give you that ability. The moderators of this group have limited privileges and that is not one of them.

This "free offer" junk is getting tiresome. Once the spam happens, it's a little too late to control. What you need to do is:

1. Make membership in the group subject to approval by a moderator
2. Set the "group settings" to require messages to be approved by a moderator
3. Change the profiles of each trusted member to allow him or her to post without moderation.

That'll fix it!

This has been discussed here A LOT in the past. The problem is that the moderators don't have the controls to do that!

If it really bothers you, there are alternative Yahoogroups, including the [LoopSkyWire] group which I think is even run by one of the moderators of this group, created because of this group's limitations on moderation.

So, stick around if you can stand the spam, or try the other group if you can't. Or both.

I find old Yahoogroups worthwhile even if they are span-infested, because they often have a decent archive of pre-spam messages worth reading and may have goodies in the Files area worth checking out.

3516. 80m skywireloop unusable on 20m

Yahoo group: SkyWires
Date: 2009-07-06 14:56:19 UTC
From: John Orzel
Topic: 3516 Message: 3516

The literature and word-of-mouth say that a skywire is usable on the fundamental and all its harmonics. I have found this to not be the case, however. My loop tunes and gets out extrememly well on 80, less so on 40, and is noisy and unusable on 20, where I have to go to a dipole juat to hear and be heard.

Any advice?

J.

Hello John,

The very best solution is to use open feederline and a symmetrical L or
double L antennatuner.

Optimal SWR, optimal efficiency, optimal results.

Have a look at my site www.remeeus.eu

3526. High Noise Skywire

Yahoo group: SkyWires
Date: 2009-07-26 05:42:31 UTC
From: John Orzel
Topic: 3526 Message: 3526

I have a skywire I use as a backup antenna cut fullwave for 3900 mHz. It is fed with ladder line to a tuner and then to the rig. It tunes very well on all bands but is very noisy compared to other antennas, especially at 14 mHz and above, where the noise level is so high the antenna is unusable. For some reason at 160m and 75/80m it will tune and perform best when one end is left unconnected. It will not tune on 160 and does not work as well on 75/80 when both ends of the ladder line are attached. It works better on 14 and above when both ends are connected but the noise level is still too high to be a practical antenna.

What can I do to make this a better-performing antenna and to cut down on the noise level? Is it better to feed it with coax instead of ladder line to a tuner/balun? What about counterpoises?

what are you using for a balun? I run an 80 meter loop up at 30 ft, fed with 600 ohm ladder line to either a johnson matchbox or a 4 to 1 voltage balun and a L network tuner. Antenna is super quiet either way and performs as it should.
I tried feeding mine with a 1:1 balun in stead of the 4:1 and it was really noisy that way.

John,
Is the loop ant. about 258 feet ?
If it is, it sounds like the system (Ant., feedline, tuner, balun) may be unbalanced for some reason.

From: bob engle
Topic: 3529 Message: 3529

Hi John,
 I have had a similar experience.
Check to make sure you
have continuity thru the feedline and loop...my guess is that one side
is broken somewhere and it is acting like a long wire this was my very
noisy problem.
 If you have continuity (note don't check through the
balun)then switch the connections to the balun by marking one side of
the twin lead and hooking it up alternating connections if it changes
then you may have an unbalance problem!
Next try an external 4 to 1 balun...I have had my balun fried due to lightning.
Don't expect much on 160 from the 3,9 MHz loop fed as a loop . the only way I could get
mine to match was tieing both ends of the twinlead together and feeding as a single wire.
hope this is of some help.

A 1 wl loop is a very good antenna but a 2 wl is even better :-)

It depends on what you wanna do with the antenna . with 15 m over the earth it will be a cloudburner so only good for local contacts

If you make a very big loop . say 4 wl or more you will have a dead spot over the antenna so local signals are lousy .. And for dx the angle is not low enough so for dx it is also useless .. A 2 wl lop would be a good thing for both . local on the 2 lowbands 80 and 160 . and with 15m over ground from 40m and up it would be a good dx antenna .. Not in every direction cause the lobes split in different directions .. but where one of the lobes fires there is a good dx signal :-)

I would try 1 1 wl or 2 wl for 160 ..

You can model it in mmana easy and see what you get ..

And the soft mmana is free

Or tell me what you wanna erect and I will make a model on my pc and send it to you

With the luxury of six towers, think about putting up two or three big loops with different shapes. This will allow you to shift the gain lobes in different directions and fill nulls (40m and up).

Best to model this in advance. Wire is relatively cheap.

A center mast and 5 long wires in different directions ... feedingline would be a 5 wire cage

Formally know as a v-star .. You can switch directions in different ways cause you can feed every wire against another

Every wire can be a dipole or a v-antenna depending what is the other wire

See in rothammel antenna book

Altogether would be a great lw-antenna (vertical with tophat) against ground

About 3 of 4:

I wrote one of the authors of full wave loops.

I was told that two and multiples thereof would not be good (harmonics???)
Not sure.

Also was told that an odd # is ok.

I put up a full wave loop for 160 meters. The author stated 529' (based on
some mathematical formula).

I put up 552 feet and it tunes great on all bands.

Somewhere (and I sure would like to see the link to the information!)
I had seen that a three-wavelength 160 Meter loop (or 5WL, 7WL, etc.) was a good target.

But again, I DO NOT KNOW. But I would like to learn

I have the room to put up a five-sided loop antenna in an open field. I now have two 45-foot guyed supports in place that would be the South side of either a one-wavelength loop or something larger, in the shape of a five-sided loop. (Trying to be a little closer to a CIRCLE, here.)

But, if the proposed three-wavelength loop's yield would be no better or possibly a poorer antenna than a one-wavelength 160 meter loop... What's the point?

My "related question" is: Would a three-wavelength 160 Meter loop work as well or HOPEFULLY better than my present one-wavelength loop(s)?

My present masts are about 40 or so feet high, so this would be the limit for any expansion. (So, yes, it would be too short. -But this is OK.)

My main desire is to BETTER the performance of the existing antenna, obviously. At the present time, the 160-Meter loops work extremely well on all bands, and seem to offer surprisingly good performance on the higher bands such as 20 and 17 Meters, as an example. (I only run 100 Watts maximum, and I can work any station that I can hear. I seem to hear as well or better than neighbors with beam antennas. -All this with no large investment and no antenna to have to TURN!)

So, am I better off sticking with a "relocated" 530 to 550 foot loop, or would a 1590 to 1650 foot loop be worth the trouble?

-My present loop antennas are being encroached by the fact that the trees are growing into them, so I need a plan. (This is why I must relocate the South loop.)

I would be feeding the "new loop" with about 200 feet of window (ladder) line, so there's be no appreciable loss.

Ideas? (Thoughts?)

Thank you! -Mike- KOJTA

My main loop is 467' fed with ladder line - works great on 40 thru 17 & OK on 160 & 80. The length was determined by what would fit.
Definitions Great: DX contacts. If I can hear 'em I can work 'em.
OK: I can make contacts.

I suspect that going from a 1L loop on 160 to 3L would improve your lower band performance but you'd be introducing a lot more lobes / nulls when operating on the higher bands.

Check out my loop photo / drawing on QRZ dot com - N4BCD

Topic: 3537 Message: 3542

Hello Mike,

My loop is 1,5 WL for 80 meters. On my site I have some photos.

When you build a 3 to 4 WL loop for 160 meters at about 40 feet high, you will get a better DX antenna for 160 meters and perhaps on 80 meters. However, on the higher bands (40 and up) the radiation of your loop will be very much distorted. In some directions it will work fine, but in other directions not.

It just what you want:
DX on 160? Then try a 3 to 4 WL for 160. DX on 40 and higher will be less than what you have experienced now.
DX on 40 and higher? Then stay at your 1 WL on 160 and use the loop on 160 for local contacts upto 750 miles.

From: Zephyr
Topic: 3554 Message: 3554

Greetings fellow hams,

Thanks for having me in your group. I want to pick your brains already :)

1. If you could choose a city apartment rental floor from which to work DX (and local) on all HF ham bands to include 160m (and VHF & UHF), which floor would you choose? This includes operating from indoors, and from a balcony or fire escape. Let's assume for simplicity's sake that any floor you choose has a clear line of sight to the horizon in at least one cardinal direction. (The apartment building isn't surrounded on all sides by taller buildings.)

2. Which floor would be the lowest floor you would consider?

3. Is there such a thing as a floor that's too high for good radiowave propagation? (Let's be reasonable. There is no Tower of Babel Apartment Complex in this city ;)

4. What if you could choose any rooftop from which to operate from time to time? How high would your rooftop be? How many stories?

5. What kind(s) of antennas not permanently installed would you use?

Thanks in advance.

73,
Frank

Hi Frank,

I assume you are talking about HF antenna performance. Too many
red-herrings to answer definitively. Basically an antenna should be as
far/and clear of surrounding objects as possible to obtain predictable
radiation patterns. Height above ground as you are defining it ... eg.
which floor of a building ... or how high the roof, is really for the mosty
part,irrelevant for HF. If you are talking VHF/UHF then actual height
above ground has meaning ... as radiation is almost exclusively line of
sight. HF is a different situation ... in that line-of-sight is not
relevant. For example: A typical antenna might be a dipole mounted on a
30 ft tower. It could be located on a open field in one instance and on
the top of a flat roof of a 30 flr apartment in the other. The radiation
pattern of the 2 antennas would for the most part be pretty much identical

at a distance ... e.g. out of the line of sight. Any difference would be due to different 'ground' characteristics represented by the earth out in the field vs the 'ground' represented by the building structure it is sitting on.

As soon as you bring the HF antenna into or adjacent to the building all bets are off in terms of any predictability of performance. You have to work with what u got. However, the same rule applies ... keep the antenna as free and clear of surrounding objects as possible. I lived in a 9th floor apartment which had a 12 x 5 ft and ended up with a folded up dipole of 20m ... held out as far as possible from the building by thin ... almost invisible sticks. I worked many stations on 20m cw and psk.

Working lower frequencies was futile ... unless of course i want to work the guy in the next building. Performance is nJot predictable with these kinds of dramatic antenna restrictions.

Jim,
ve3CI

3556. RE: [SkyWires] operating from apartments

From: Michael Weinstock
Topic: 3554 Message: 3556

Hello Frank,

If I were in your situation, I would desire the highest floor possible for multiple reasons:

- Most VHF/UHF communications are 'line of sight'. Increasing your height above ground and increases your 'line of sight' and therefore your effective range.

- Increasing height usually helps get you above obstacles which may block signal paths, particularly for VHF/UHF.

- For HF comms, a low angle of radiation is desirable. If using horizontally polarized antennas, height above ground is a major factor in determining your angle of radiation. This factor becomes more critical with decreasing frequency as height above ground as a % of wavelength decreases for any given static electrical length of antenna.

- Getting above other antenna and electronic equipment will decrease the likelihood of causing interference.

You have not mentioned if you need to use 'stealth' antennas or not ? If you do, I think verticals are likely to be a good choice, in particular if there is a heap of metal on the rooftop that you could use as a ground plane. If no ready made ground plane is available, then you need to consider radials of some sort. Also, chances are an auto ATU at the feedpoint is going to make things easier especially if your antenna is not resonant at all desired frequencies of operation and if you are going to feed back to your transciever using coax (which I suspect is a given).

For HF (especially lower frequencies), since you are so high above ground, I would strongly recommend using a 'tuned counterpoise' ground solution. MFJ sell an artificial RF ground tuner "MFJ-931" that performs this task, or you could homebrew if so inclined. The tuned counterpoise ground will also assist if you decide to use horizontally polarized antennas for HF if there is any RF in the 'shack'.

Every installation poses its own set of challenges and requires its own assessment usually with some level of compromise. For non permanent antennas with no rotator, I think verticals are a good choice, especially for VHF/UHF. For HF, it is going to depend on what you can install, whether you choose horizontal wire antennas or verticals, or both.

Since this group primarily deals with horizonal loop 'skywire' antennas, I want to mention this possibility as well. What is the shape and circumference of your the rooftop ? Any chance of a full wave 160mtr loop raised above the circumference of the rooftop ? Feed that with ladderline

or home brew open wire feeder to a 4:1 balun and quality ATU combo in the 'shack', and you would have yourself a very decent HF multiband antenna that is easy to construct, cheap in terms of materials, and a great all round performer.

Michael,
Thanks for these great ideas. I'm asking because I'm currently hunting for an apartment. I will most likely need stealth antennas. Each time I ask about an apartment, I also ask about roof access. Even with roof access, I don't plan on leaving expensive antennas up there for long periods. This is New York City. Stuff left out has a strong tendency to walk away on its own. Also, the majority of apartment buildings here are constructed of concrete, brick, or brownstone.
I looked at one apartment on the 5th of 5 floors which has roof access. However, it's surrounded on 3 sides by taller buildings and has clear line of sight to the western horizon. If I had a choice of one direction, I'd prefer clear LOS to the east for DX purposes.

Another apartment I looked at is right across the street from a nice park. The trees aren't very tall though. And the apartment is on the 4th of 4 stories, a side apartment facing a six story building-- with no roof access. Below the metal fire escape are some No Parking and other street signs. I thought these would make possible attachment points for wire antennas, aside from the fact that they're made of metal. A fellow ham in another group brought up trees. It's probably feasible to run a really long wire from the fire escape all the way to a tree across the street in the park. I would only do this late at night though. I don't recall if there are power lines running parallel to the street.

Speaking of MFJ's ground tuner, it should be ok to use a different brand of tuner with MFJ's ground box, correct?

It looks like I'll keep searching for a top floor corner apartment with a balcony or fire escape and roof access. I hope to find one that isn't surrounded by taller buildings. Wish me luck.

Topic: 3554 Message: 3558

Hi Frank,

When dealing with taller buildings around you, I'd be taking into account how much of the horizon they obscure (VHF/UHF line of sight) and what the angle would be between your antenna and the tops of the other buildings (angle of radiation for DX work). The more in the clear you are the better.

Metal fire escapes could potentially be used to your advantage. You could tie into them as part of a tuned counterpoise, and/or they can still be used as attachment points for wire antennas. When using these as attachment points, I would use dacron rope and strain insulators to get enough distance between your antenna and the metalwork.

> A fellow ham in another group brought up trees. It's probably feasible to run a really long
> wire from the fire escape all the way to a tree across the street in the park. I would only do
> this late at night though. I don't recall if there are power lines running parallel to the street.

There are plenty of hams who use long wires, off center fed (OCF) dipoles, windoms, loops, zepps, etc successfully, and trees can make good attachment points for HF antennae. The downside with many of these antennae as far as I am concerned is directionality of the radiation pattern with increasing frequency. The higher the frequency, the more the main radiation lobes concentrate down the direction of the wire (long wire in particular). This is one of the advantages of the 'skywire horizontal loop'. The radiation pattern is roughly omnidirectional over a wide range of frequencies.

Prudent use of insulators, and methods to cope with wind, and ice loading are required, as is a RF counterpoise to electrically 'push' against. I have used springs to provide some 'give' in such systems, but in this part of the world, ice loading is not an issue. From what I remember of NY, it is an issue. If there are power lines, obviously never cross them. As for running in parallel, best avoided but you might not have a choice. If so, the further you can get away from them the better.

> Speaking of MFJ's ground tuner, it should be ok to use a different brand of tuner with MFJ's ground box, correct?

Absolutely ! The last time I checked, RF was still brand agnostic ;-)

You are probably going to need a few antennas to give you full spectrum ham band coverage. For example, a suitable length long wire/OCF dipole, would probably be good for 160, 80 ,60, 40 and then start to get too directional for the upper HF bands (unless the directionality was working in your favour). A vertical for the upper HF bands and perhaps 6 meters could fit

the bill for those bands.. Verticals for 2mtrs and 70cms would work.

Let us know how you go and GOOD LUCK ! :-)

Subject: Re: [SkyWires] operating from apartments

Michael,

Thanks for these great ideas. I'm asking because I'm currently hunting for an apartment. I will most likely need stealth antennas. Each time I ask about an apartment, I also ask about roof access. Even with roof access, I don't plan on leaving expensive antennas up there for long periods. This is New York City. Stuff left out has a strong tendency to walk away on its own. Also, the majority of apartment buildings here are constructed of concrete, brick, or brownstone.

I looked at one apartment on the 5th of 5 floors which has roof access. However, it's surrounded on 3 sides by taller buildings and has clear line of sight to the western horizon. If I had a choice of one direction, I'd prefer clear LOS to the east for DX purposes.

Another apartment I looked at is right across the street from a nice park. The trees aren't very tall though. And the apartment is on the 4th of 4 stories, a side apartment facing a six story building-- with no roof access. Below the metal fire escape are some No Parking and other street signs. I thought these would make possible attachment points for wire antennas, aside from the fact that they're made of metal. A fellow ham in another group brought up trees. On Wed, Oct 7, 2009 at 19:51, Michael Weinstock
<mweinstock@...> wrote:

Hello Frank,

If I were in your situation, I would desire the highest floor possible
for multiple reasons:

- Most VHF/UHF communications are 'line of sight'. Increasing your
height above ground and increases your 'line of sight' and therefore your
effective range.

- Increasing height usually helps get you above obstacles which may
block signal paths, particularly for VHF/UHF.

- For HF comms, a low angle of radiation is desirable. If using
horizontally polarized antennas, height above ground is a major factor in
determining your angle of radiation. This factor becomes more critical with
decreasing frequency as height above ground as a % of wavelength decreases
for any given static electrical length of antenna.

- Getting above other antenna and electronic equipment will decrease
the likelihood of causing interference.

You have not mentioned if you need to use 'stealth' antennas or not ?
If you do, I think verticals are likely to be a good choice, in particular
if there is a heap of metal on the rooftop that you could use as a ground
plane. If no ready made ground plane is available, then you need to
consider radials of some sort. Also, chances are an auto ATU at the
feedpoint is going to make things easier especially if your antenna is not
resonant at all desired frequencies of operation and if you are going to
feed back to your transciever using coax (which I suspect is a given).

For HF (especially lower frequencies), since you are so high above
ground, I would strongly recommend using a 'tuned counterpoise' ground
solution. MFJ sell an artificial RF ground tuner "MFJ-931" that performs
this task, or you could homebrew if so inclined. The tuned counterpoise
ground will also assist if you decide to use horizontally polarized antennas
for HF if there is any RF in the 'shack'.

Every installation poses its own set of challenges and requires its own
assessment usually with some level of compromise. For non permanent
antennas with no rotator, I think verticals are a good choice, especially
for VHF/UHF. For HF, it is going to depend on what you can install, whether
you choose horizontal wire antennas or verticals, or both.

Since this group primarily deals with horizonal loop 'skywire' antennas,
I want to mention this possibility as well. What is the shape and
circumference of your the rooftop ? Any chance of a full wave 160mtr loop
raised above the circumference of the rooftop ? Feed that with ladderline
or home brew open wire feeder to a 4:1 balun and quality ATU combo in the
'shack', and you would have yourself a very decent HF multiband antenna that
is easy to construct, cheap in terms of materials, and a great all round
performer.

From: Bill
Topic: 3560 Message: 3560

I need some help with an antenna. Due to money constraints I may try to use a Wilson 1000 trunk lip mount CB mobile ant on a thirty foot metal pole for my cb base station. I will probably have to use some form of ground plane with it. Just wondering if anyone else has done this and could use some ideas for constructing a ground plane. Will also try to use this for SWL and might even try with scanner!
Just cannot afford to buy a " real " base antenna.
If this is to far off topic - thank you anyway.

If you can scrounge up about 37-38 feet of wire you can make a nice gain antenna for 27Mhz. Make it in a loop with a couple of cheap fishing poles from walmart.

The antenna you describe can a decent antenna - I am assuming that it is a 1/4 wave antenna. First thing I would do is find yourself a 8-9' long wihip to use as the vertical part, then at the base, you can attach 3 or four radials sloped away at a 45 degree angle. This will work fine as an antenna...I have made similar antennas for 10M and 6M...and they work nicely.

Scott

Well first of all, I am really impressed with everyone for not hounding this guy for being on 11 meters. A lot of hams came from there, including me. Perhaps if we would all just show that we aren't all better than you, and all stuck up, more would come our way.
I think the mobile antenna will do fine if you use three or four 18FT radials on it. They can be made of wire with an insulater at the ends and then used as guy wires to hold the mast up.

I have used mobile antennas in a fashion similar to this many times and this should work just fine.
Even ground mounting mobile antennas for HF do a good job, with ground radials, elevated counterpoise, ground plains or what ever you will to call them.

3565. Going QRO

Yahoo group: SkyWires
Date: 2009-10-13 16:16:08 UTC
From: Aaron
Topic: 3565 Message: 3565

So I decided this winter I will be QRO finally. My SGC-239 out at the barn does great but 100W 160M just doesn't cut it. The tuner will only handle 200W PEP. I need to reconfigure the setup from the shack all the way to the feed point then.

I seem to get a bit of noise on the higher bands as well, 30M is about unusable even on my Corsair II, so I think I might try a 4:1 at the feed point and see if that helps.

Ladderline to the shack is out of the question, too much routing and stuff out in the yard to make it work right. So I am now back to direct feeding with coax with my potential setup.

Now the big question... what tuner to get?? I thought about the SGC-235 but that only gives me 500W PEP 160 - 10, it does allow me to put it out at the barn. Also expensive.

PALSTAR AT-AUTO, Legal limit 160 - 6, very expensive and sits in the shack. Think it might be the nicest Auto tuner on the market.

Looked at the LDG 1000, had terrible reviews.

Then again I could go with a good roller inductor but I go jump around a lot and spoiled on this memory tuning stuff. Also what's going to happen on 160M with a 4:1. I figure that's going to put me somewhere at 20 to 12 Ohms impedance and not too sure how that's going to affect the performance.

Thought it would be best to kick thsi one around before I start buying stuff.

You might just stick 2 copper pipes under the antenna 90 degrees from the antenna and each other. I think the way the Wilson is loaded a ground plane angle will not affect you SWR much but it will change your take off angle. Also a A99 ground plane kit should slide over 1.5" pipe I think. That would work too. Best bet is to throw something up and try it.... might be surprised.

The first antenna I built was for CB and I used half of a super scanner element (cause that's all I had) and a 3 speed bicycle rim for the ground plane. Work most of the country on 5 watts.

Hi Aaron,

I guess what you are about to find out is that QRO has it's own problems. The system you have now ... the automatic coupler at the feed point allows you to 'go every where with impunity' .... as long as you keep power within reason ... eg. in your case 100 watts.

Even if you could use a parallel feed line I am sure you would find many frequencies you could handle at 100 watts that will be out of the question when running QRO. The fact is, when you go QRO you will not have the ability to jump around on bands and frequencies as you presently enjoy.

Your alternatives are:

1. find or make a high power alternative to your SGC-239.
2. go with a hybrid system ... e.g. SGC-239 for general coverage at 100w and a switched in fixed system (close to the antenna) for QRO on your favorite band/frequencies.

Jim, VE3CI

Hello Aaron,

Make a tuner yourself. It is less difficult as you might think and it will give you a lot of satisfaction!

Many books and magazines are written about antennatuners.

The most simple one is the LC-/Reversed-LC tuner. Please read QST September 2006, pages 56, 57 and 58.

I just built two LC antennatuners for my 73 ft vertical. They cover the 160 untill 15 meterband and will easily handle at least 1,5 kW on all bands. Costs: not more than $250 for both the tuners.

Hi Aaron,
You may be one that can learn from other's mistakes (I usually have to pay for my own and learn slow). Recently I was enjoying my home brew amp that uses eight MRF-151G MOSFETS. It is over built with low power and SWR protection. Since it would do 2.4KW RMS or 3.2KW PEP into a dummy load I felt it was built proof running it at 1.2KW to 1.4KW. I do not like tuners in line and take pride in my resonant antennas. The one I've been on is flat at 3.95 and the needle quivers at 3.97. It is an inverted V with a legal limit ferrite type balun. Having just come home with a Swan ST-1A tuner I started playing on 14.24 and 7.24. The 20m tuned up easy and worked fine (probably heated the balun a bit?) but the 40m tuned a bit slower. All seemed well until well the SWR reading jumped from flat to infinity and there was a flash in the amp that I hoped was a relay.
I had forgotten that there would be a lot of heat for the balun to dissipate. Baluns are not so good at dissipating heat! The flash was one of the MFR 151Gs popping apart. The amp uses eight of them at $115 each plus shipping. After testing I decided two were defiantly bad and I may have gotten off cheap only having to get off $240 and change. A $950 transistor bill would have been a hard spanking.
So I guess what I'm saying is things can get expensive when we forget simple things like getting off resonance causes heat and the heat has a relationship between the power level and how for off resonance we are. And even with built in protection in an overbuilt "bullet proof" amp things can get nasty faster than we can flip a switch. QRO can get expensive if we get lax on the simple things.
Abe
P.S. I'm now using an RG-8 air wound balun feeding the 75m wires and included a 40m set of wires on the same feed point. I hope to get a 235' to 345' piece of wire up soon.

Hi Bill,
Want a real high performance base antenna for almost nothing? It will be a 5/8 wave ground plane optimized for a great impedance match and low angle signal radiation (low SWR and great low local and skip lobes).
The parts will be:
PARTS:

1. a 3" piece of ¾" PVC pipe

2. about a foot of 14 gauge enameled wire (you can use a white or black insulated wire from a piece of romax but it will change the hole spacing on the PVC pipe)

3. about 125' of any non insulated wire (you can use insulated wire by making all 5 radials 5% shorter)

4. feed line of coax that will reach from antenna to transmitter with a PL-259 at one end

DIRECTIONS:

1. Take the 14ga enameled wire and wrap 11 turns (this should leave an inch or so at each end as the coil should be ¾ of an inch) around the PVC pipe ending with an inch or two of wire left at each end of the coil. This will be about a 1.588 microhenry coil
2. mark and drill a small hole in one side of the PVC pipe at both ends of the coil when the coil is about centered on the pipe
3. drill a small hole all the way through (both sides so 2 holes) ¼" from one end of the pipe
4. drill 2 holes all of the way through ¼" from the other end of the pipe at 90^ angles (this will be 4 holes, the 4 radials going in 4 different directions.
5. put the wire at the ends of the coil through the holes at the end of the coil and pull them out the ends of the pipe, the coil should be tight
6. take a 23' wire and feed it through both holes at one end of the pipe, tie and solder it, also soldering the wire from the coil to it as this is your vertical radiator. And use about 3" of wire to make a small 1" loop at the other end, this is to tie a string or rope to.
7. take 2 wires 52' long and feed them through the 4 holes at the other end of the pipe, centering the wires so about 26' of wire is coming from each hole (you should keep these as close to the same length as possible). Solder the 2 wires together where they cross in the pipe.
8. strip the shield back a couple inches and solder the center to the wire from the coil as far in the pipe as you can. Solder the shield to the 4 radials and push the center farther into the pipe being very careful the shield and center do not touch.
9. when you pull this up by the vertical radiator (rope over a tree limb or convenient high object works fine) it is best to get the coil 17' or 18' off the ground (higher is not your friend here as this height is the ½ wave point that will give you the best take off angle). The 4 radials should be tied with string to points that will let them angle down at about 45^, this is what will give you a 50 Ohm feed point. Check your new antenna and you will be

amazed at tah SWR and even more amazed at how well it performs.
10. NOW LOWER THE ROPE (you can leave the 4 radials tied in place) SO YOU CAN SEAL THE COAX WITH A GOOD SEALER, I WOULD USE MARINE GOOP OR BETTER FOR THIS. Sealing is a must! Or the coax will be junk very very soon.
Hope you have fun with this. I can give you other coil sizes if you need them, say you have 1" pipe but not ¾" pipe or ½" and not ¾". The radial will stay the same and are designed for 27.2 MHz.
I design and build a lot of antennas for others and myself. Most are variants of something from one of the ham books. This may be a good time to invite you to join the ham ranks. The code is no longer required and if you have been on 11m for long you will already know a lot of the test questions. As a tech you can use 200W on 28.3 to 28.5 SSB. There should be folks in your area to help you along. When you upgrade to general you can use 1500W and a whole new world of HF fun becomes open to you.

Hi guys, the question i have is about my Loop that i have been using for about 2 years now.It is 263ft long as this you will see is determined by the shape of the building, bit of a fluke.

I live in an upstairs apartment in a block of 4 and due to local restrictions i cannot have any outside antennas.

You may ask then were is this loop that you have had up for 2 years,well it is tucked inside the plastic rain gutter all around the building.

The shape of the building is an "L" shape like 2 oblongs at right angles to each other

I feed it in the the sharp corner with a 4:1 balun and then about 20ft of 50 ohm co-ax into the shack,all of this feeder is in the attic space. It works quite well but i am being constantly being told that i should feed it with ladder line.

My question to you guys is how much benefit will i have if i feed it with the equivalent length of 450 ohm ladder line and then into the 4:1 balun.

I have to consider that in the attic there are all the TV antennas so i do not want any problems there as at the moment all is clear.

Thanks in advance.

Hi Ken,

I have a 1,160 Ft. Loop on my farm, I started feeding it with ladder line like they all say so, I kept getting RF in my home, in my wife's clock radio at 2 AM

I tried Ferrites, Finally I bought RG-213 Coax, I run it from my tuner 80 feet out to my antenna base, then a balun and up to the feed about 55 feet with ladder line,

I have had no difference in signal reports. My experience is less RF problems using coax, I don't think you will find a difference,

Hi Ken,

There is a great loop modelling program called rjeloop4.exe available at the following URL:

http://www.smeter.net/antennas/large-transmitting-loop.php

The reason I'm suggest this program is that it allows you to model the differences between using 50 Ohm feedline versus 450 Ohm feedline. Where the loop is an odd multiple of a 1/2 wavelength at a given frequency, there will be a very high impedance presented at the feedpoint. There is potential to significantly reduce the feedline losses by moving to openwire feeder or ladderline by virtue of lowering the impedance mismatch between antenna and feedline as well as using a feedline with lower losses than coaxial cable.

As for the potential for causing interference... theoretically, balanced feeder should not radiate and hence it should not be a source of interference... but this is the case only as long as it is truly balanced with equal and opposite currents in each wire that cancel each other out. If your like me and do not have the luxury of access to an RF ammeter, an old timer taught me a neat trick shortly after I got my licence. Solder some short flyleads onto a couple of torch/flashlight bulbs and place them in each leg of the feedline. I suggest doing this at the balun for convenience. Tune up on low power and then slowly increase power levels until the bulbs start to glow. The amount of power needed before the bulbs start to glow will vary with frequency due to changing impedance at the bulb insertion point into the legs of the feedline. Equal current in each leg should mean equal brightness from each bulb. If the bulbs do not glow evenly, then it is reasonable to assume your feedline is unbalanced and hence radiating. You may even get different results on different bands.... balanced on some and unbalanced on others.

Another trick I was taught was to apply a helical twist to an open wire feeder. This is easier to do with wider spaced open wire feeder as compared to commercial ladder line, but it still can be done on the commercial stuff. The reason for doing this is to try to even out the exposure of each leg to items (such as downpipes, gutters, wires, etc) that might couple to the feedline and hence detune it such that it becomes unbalanced. This twist can also help to cancel out the effects of any local sources of interference close to the feedline as well as provide some extra physical stability to the feedline.

My suggestion is to have a play with the program... model your loop at frequencies you operate on and check the effects of changing the feedline impedance from 50 to 450 Ohms. If you are satisfied that you can improve

the efficiency of your setup by moving to ladderline, then do so. Once you have installed the ladderline, tune on low power and check the current balance using the inline torch bulbs. If you are satisfied that the feedline is adequately balanced, then theoretically, it should not be radiating and hence should not be a source of interference.

That said, when you start to radiate extra watts as signal strength froma low loss feeder setup rather than heating the coax, you might find greater potential for interference on transmit. In that case, turning your power down should theoretically get you back to similar field strengths on TX that you had with coaxial feed and hence hopefully no interference. On RX you would have the benefit of the extra efficiency in the system.

Let us know how you go.

Rule 1 to live by.... If it's not broken, don't fix it! If you are satisfied with
the performance of your present antenna and it's not causing any RF
complaints I'd be really reluctant to make any changes. At the very least,
try to make any changes easily reversible. That way, if the changes cause
problems to arise you can put it back like it was without major labor and
cost issues. Having said that, it's possible one of our local Group Gurus
may be able to tell you how to quadruple the performance of your antenna.
Good luck with it.

Harold

Thanks guys on all the points and i will give it a go.

I must admit to having a laugh to my self about the flash light bulbs as when i was first licensed back in`63, it was a trick we used to use then for tuning up an end fed long wire we called them loop lamps and i won first prize at the local radio club in the annual construction contest for my bare faced cheek for having the nerve to enter it.

It is quite easy to play with this loop as i can get to the feed point by going through the landing window onto a flat roof area.

Judging by your thoughts i do not think that there will be much either way as the feeder is so short and if i use ladder line then it will have to lie along the rafters horizontally so this in it self will unbalance it.

I will have a try and let the group know what happens.

Also i will check the modelling program too and see what comes of that.

Michael just to say thank for the link on the loop calculator.

It is a great and very simple to use and also very informative and using either 50 ohn Co-Ax or 450 ladder line feeders well there seems to be very very little in it, so other than playing and that i do enjoy i think that as others have said "If it aint` broke don`t fix it".

My pleasure Ken.

Re the program, I really like that it explains much of the theory in addition to the modelling and it is simple keypresses to vary the frequency of operation over a wide range. Lets face it... we are more likely to go band hopping with other parameters constance than we are to fiddle the feedline length each time we change bands ;-)

From the additional info you have provided... short feedline, rafter mounting of balanced feedline and modelling the differences, I would be inclined to change my mind too and leave the coax in place. At my QTH, as I load up an 80mtr loop on 160mtrs, using the balanced feeder provides me with about 3db less loss in the system as compared to coax. That is enough to make it worthwhile for me... but everyone's mileage will vary.

It is very much a case of competing priorities and practicalities.

Subject: [SkyWires] Re: Advice required

Michael just to say thank for the link on the loop calculator.

It is a great and very simple to use and also very informative and using either 50 ohn Co-Ax or 450 ladder line feeders well there seems to be very very little in it, so other than playing and that i do enjoy i think that as others have said "If it aint` broke don`t fix it".

3598. Arborist Slick Line

Yahoo group: SkyWires
Date: 2009-12-09 20:22:35 UTC
From: k0elw
Topic: 3598 Message: 3598

I recently became aware of the technique arborists use to
get lines up in trees when I had an arborist doing tree work on
my lot. (Including taking down a dead tree, and reposition a line
25 ft higher than before!)

We've all struggled with tangled fish line, breaking getting snagged,
etc and spending to much time getting a line up in the air.

Arborist slick line is a wax-coated heavy string which does not tangle.
You do not coil it or wind it on a spool, just store in a bucket or stuff bag.

http://wesspur.com/throw-line/throw-line-kits.html
Here is one outfit that sells a kit.

Here is a demo:
http://www.youtube.com/watch?v=EDTNO43PbJI&feature=related

I'm really surprised I've never seen hams use or discuss this technique.

http://www.wcflunatall.com/nz4o4.htm

Sunspot group #11035 near N30W13 has grown into the largest (seven times larger than the Earth) and most magnetically complex (beta-gamma) sunspot group of solar cycle 24. At 0102 UTC the sunspot group released a small C5.3 solar flare, the largest solar flare of solar cycle 24. More small C class solar flares are possible, with a chance for an isolated medium size M class solar flare.

#11035 also produced the first partially geoeffective (Earth facing) coronal mass ejection (CME) of solar cycle 24. The CME will arrive at Earth in a approximately two days and could spark a geomagnetic storm and visible aurora. Another geoeffective CME is possible, with an associated sudden ionosphere disturbance (SID) and shortwave fadeout (SWF).

The sunspot count is 38 which is the highest of solar cycle 24. The solar flux index is 82 which is tied for the highest SFI of solar Cycle 24.

With the increased sunspot count we should see improved propagation conditions on 15 and 12 meters.

We now officially have solar cycle 24 sunspot group #11036, located near S29W19 with a beta magnetic signature. We also have solar cycle 24 sunspot group #11037, located near N18E54 with a beta magnetic signature.

We now have three solar cycle 24 numbered sunspot groups in existence at the same time, a new record high for solar cycle 24. Also the sunspot number is 43, also a new record high for solar cycle 24.

Topic: 3606 Message: 3606

Posted Thursday December 24, 2009 at 1300 UTC at
http://www.wcflunatall.com/nz4o4.htm

A new solar cycle 24 sunspot group emerged early this morning. It is located near S27E26 and appears to have a simple beta magnetic signature. If and when it's numbered by NOAA/SWPC it will be #11040.

If numbered then the month of December has seen seven solar cycle 24 sunspot groups emerge. And of course that is a new record for solar cycle 24.

The solar flux index values for December 23rd were 80.7 78.4 76.8 and the sunspot number 23.

3608. Balun or not to Balun

Yahoo group: SkyWires
Date: 2010-01-04 03:00:01 UTC
From: Aaron
Topic: 3608 Message: 3608

I have been kicking around either dropping a 4:1 or 9:1 in hope to reduce my noise level on the higher bands. Not sure if my tuner will match it on 160 with the balun, think that might drop the impeadence down too low. This may not work but thought I would get some more info on the matter before I try.

Setup:
75' Coax to SGC 239 Tuner to 35' of 450 Ladder Line to 530'ish of loop

I'm planning on putting the balun right between the tuner and the ladder line and hopefully it might balance they antenna out. I may be wrong but again that's why I am here bouncing ideas around.

Did this with a fc 1000 tuner and it worked quite good

If you have problems on 160 try to lengthen the ladderline

Hi

The best place for a balun in your arrangement "antenna > ladder line > SGC coupler > to coax" is between the coupler and the coax. In this case it only needs to be a RF choke. You can also put a RF choke on the control/pwr line (right at the coupler). This will go a long way to eliminating antenna currents on the outside of the coax shield which in turn will promote balance in the ladder line. You indicate correctly that receive noise is increased by imbalance in the ladder line and common mode currents on the coax. The choke/balun (1:1) at the coax/coupler works best at that impedance ..... who knows what impedances will be encountered on the other side of the coupler.

You want the feed line to be neutral .... that is to contribute a minimum of radiation on xmit and to contribute a minimum of RF pickup on receive. this is achieved if the ladder line is in balance and the currents on the outside of the coax shield are divorced from the ladder line/loop (e.g. choked). If the line is not balanced and coax choked ... then the feed line will act as an effective part of the antenna as it comes through the noisiest part of the environment down to the shack.

Topic: 3611 Message: 3611

I just put up a 160 meter full wave horizontal loop at our lake place. It's 536 feet of 15 Ga insulated stranded THNN fed with 450 ohm ladder line to an MFJ 949C tuner. The height varies from around 20 to 40 feet as it winds through the trees. It works really well until I try to load it on 15 meters and above. I am getting RF back into the tuner on those bands. I'm using the balanced line terminals on the tuner which go through a 4:1 balun. Any ideas on what I could do to solve the RF problem?

Hi Bill,

What is your station ground setup ?

I found a really good article the other day talking about 'ungrounded grounds'... where your station ground might be a poor RF ground with increasing frequency. Sounds like a possible match for the behaviour you are describing.

What might seem a reasonable station ground at lower frequencies could in fact represent a high impedance path to earth especially on the higher HF bands as you are reporting. If the length of your path to ground is around 1/4 wavelength on a given frequency, it will act as an impedance transformer isolating your shack from your station ground.

There are many different solutions to this problem and I recommend you take a look at this URL:

http://www.radioworks.com/nbgnd.html

I have an MFJ-931 artificial RF ground to use as a tuned counterpoise and it works great. I usually use it when I am operating portable as my station ground lead is very short in my case (about 5 feet).

I also have an MFJ-949C tuner. I think the 4:1 balun inside is rather diminuitive, but I doubt that to be the source of the problem. You could try an outboard more substantial balun.. would probably be more efficient, but again, I doubt that is the ultimate source of the hot tuner you are describing ?

Hi Bill...

I think you need to change your feedline length slightly. Sounds like it is giving you a high impedance at the tuner. Check out this article

http://www.w5dxp.com/notuner.htm

You'll get the idea; add a couple of feet and recheck. If the problem goes away, great. If not, start checking out something else.

Hi Bill,

not sure what you mean by "getting RF back into the tuner" .... but I assume your tuner/balun doesn't match your radio to the feed line very well on 15m. The time honored solution is to add some extra parallel feed line between the present end of the feed line and the input to your tuner. This added parallel feed line can be 450 ohm ... or some good quality 300 ohm feed line. It can simply be rolled in a large loop next to the tuner. Start with 5 feet and add more if needed .... each time checking how the tuner works on 15m. When you find the 15m sweet spot ... you may find it causes a problem on other bands .... if not ... leave it in. If it does cause problems on other bands ... simply make the extra line removable.

That is exactly how i tuned my 168m loop .. With 2 different lengths of wire
I can work any band

Most of them without tuner . and on the other bands swr is low so
tunerlosses and feedlinelosses are low

See loop.xls in the file area

Hi,

The problem being 15m I recommend adding only a few feet at a time. It may not take much to bring the impedance into the range your tuner/balun can handle.

Jim, VE3CI

Yes, The easiest way is to use a two conductor lamp cord.

Another option I have heard of.....

Put a trap on the far side from the feed point.....

160 would become a folded dipole....higher bands would remain a loop

I have never tried it, but have heard it works

This is something I have thought about trying.....

Anyone run it through EZNEC (or another program) to see what the patterns would look like?

I think that open at the opposide would be easier .

Now you have a bent dipole for 160 . should work better as the 2 conductor loop .

Hi,

Yes you could .... but let's be clear. From a radiation point of view you will still have an 80m horizontal loop ..... the added inductance (and some capacitance) will serve to make it easier to feed the loop on 160m. You didn't mention the kind of feed system you are presently using. If it is coax ... then you are attempting to make the feed point a lower impedance on 160m.

If you break the single turn loop (present configuration) at a point opposite the feed point then the loop will become a 160m dipole that is bent into a square (if that is the present shape). You will then have no difficulty feeding the loop on 160m. If the shape is such that there is a support at the half way mark on the loop then a relay could be placed there to make (80m) and break (160m) the circuit. Someone mentioned putting a trap at that point (i presume tuned to 160m).

Someone also mentioned using zip cord to make a 2 turn loop. You could also simply feed the loop with open wire line .... using a length that brings the impedance to a manageable value for your tuner. There, a lot of possibilities.

Hi,

As an addendum ..... all of the discussion so far has been on methods to get the RF into the antenna (e.g. the 80m horizontal loop). A further alternative would be to consider the whole loop/feed line as an antenna. I am reminded of a situation I had many years ago when I had a balanced antenna (100 ft doublet in an inverted Vee configuration) mounted with the apex 30 ft over the ridge of the roof of a 2 story house (about 60 ft total above ground). I operated 100w AM in those days. I used a balanced tuner with ordinary 300 ohm TV twinlead feeding the doublet.

It worked gang busters 10-80m .. but was just so so on 160m .... as I was interested in calling in to an early morning net. I had no problem loading the doublet on 160m ... but didn't get out that well. then I tried using the whole antenna/feed system as a vertical radiator .... the shack was in the basement and the feed line went out the basement window ... up the side of the house ... up the 30 ft mast to the doublet. I simply loaded the shorted feed line against ground (using the plumbing in the basement). the performance was a great improvement ... and I had no difficulty working the net in the mornings.

Just another idea. Feed your feed line as a vertical and let the loop work like a capacity hat. simple to try.

Hi Steven,

My understanding of the trap option is that traps should be tuned for the lowest frequency of the band in question.

No do not use a trap use a high voltage switch or relay .

You will have a lot of losses with that trap .

A friend from me did this test he had a 80m loop ha made the feedingpoint outside in the garden

So the opposide was near his window .

A short piece of ladderline to his window ended in two bananaplugs he could make tests on different bands with or without trap open and closed . Best was let the trap away . Finally he had an arrangement that worked very good

He had a bridge that he could close or open the ladderline and that´s it

Just turn your loop around feedingpoint away from you and you can reach the magic point easy

Well the 1:1 didnt do anything special... still getting high noise on 20, 30, and 40. Think tomorrow if I have time I am going to rewire my tuner box and the cables and connectors. The only 2 other options I know of at this point is either try another or aditional 4:1 or 9:1 like I mentioned.... or try running direct coax feed again. I know there is room for improvement just not sure where or what is the key just yet.

Balun maybe can reduce noise IF the feedingline is acting as a second receiving source

A balun may improve balance on the ladderline and the line will not radiate (or receive)

3634. cage loop

Yahoo group: SkyWires
Date: 2010-01-27 20:12:21 UTC
From: kb5vwz
Topic: 3634 Message: 3634

Hi, I am new to the group so I have a question for the collective.
I am planning my station for when I return to Texas. I have ready to install 4 towers next December when I get back. My idea is to assemble a cage loop strung between the 4 towers. The towers will be 40 feet apart in a square set up. My idea is to build 4 cage loops roughly 40 feet long, make a short jumper across each corner and feed this monster with coax at one corner. The elevation at each elevated mounting is planned to be at 39 feet. Two towers will have beams above, (VHF, UHF, the other with a tri-bander and VHF vertical) No, I am not considering a 4 square vertical array as two towers are up against a metal building. I have read nothing but good things about loops when installed elevated above ground at least 40 feet. I have heard DX stations ask for comparisons too and from my receive location they have sounded better. I have also heard stations using the DX blaster dipole set up, therefore the idea of the cage loop.
I also have a SGC 230 antenna coupler I might connect to this project so that I can get some multi-band operation.
Thoughts, Ideas, comments, are welcome.

Hi Tom,

I have had loops of all sizes, my first was for 80 meters, If you have room and can get 260 some feet of wire up for 80 M, you will not regret it.
My loop now is 1,160 feet although there's no need for that big of one, They do very well and I have mine a little over 40 feet high so your height will work. You can see mine at www.freewebs.com/w7kol 73's Mike

Hi Tom,

Just to be sure I understand .... you are building a horizontal loop approximately 160 ft in circumference which will be supported by 4 towers 40 ft in height. The loop will consist of 4 cage elements similar to the cage elements in the DX Blaster dipole.

Generally speaking, the cage elements when used in the dipole configuration are shorter in length than a single wire to obtain resonance at a particular frequency ... the resonance is broader (less sharp) making for operational convenience. If using a single wire ... I would expect a 160 ft loop to resonate somewhere below the 40m band .... e.g. 6.3 mhz. It will be interesting to predict where this loop (with caged elements) will resonate .... perhaps in the 60m band. However, I would expect the radiation pattern to be similar to a standard wire loop of similar dimensions .. although overall efficiency will be a little better ... the testimony of caged dipole users seem to endow them with special powers hi hi. I will be especially interested in knowing what the caging of the elements will do to the natural resonance of the loop ... it is not something I have seen published anywhere.

After all the work involved in caging the elements and stringing them up between the towers the SBC coupler will be very useful getting the loop working efficiently on all bands.

Wondering?

By cage loop, do you mean a circular antenna with anywhere from 3 to 6 wires in a circle around some sort of support? If you ahve a ARRL Wire Antenna Classics book around, the story starts on page 1-15...

Hello All.

I'll bet I'm asking for trouble, but has anyone built chokes or baluns from RG6 coax? This will be used with an FT-857D at 100W or less.

73 de David ki6fbx k

I logged onto ARRL but was not able to find the reference...but yes to your question of 6 wires in a loop config.
Hopefully someone steps up with a computer model.....

Betreff: RE: [SkyWires] cage loop
Wichtigkeit: Hoch

Hi guys I also am new to this group but an old fart ham. hi hi

I want to put up a loop around my property I have a big lot should be abt 800ft.

What would be the best way to feed it. I have an ant tuner that will feed bal line wire or coax

ART 15.

Found some references on the www for cage dipoles which had some good info. I have not found any other references of anyone using a loop as I propose.
From what all the reading I have done, the band width at resonance should be very wide (broad banded),
I have the ARRL version of Enzec, but I am struggling here...(hint hint)
I started out using 1005/freq (7.000) to come up with starting point,(right out of the ARRL book) then thought about broad banding the thing by using a cage..(large diameter=band width) So here I am.

I for one have not seen anyone do this, at least not on the web, so one of two things, it will not work or I have come up with a novel idea...

Do we not have any moderators on this site??? Getting pretty bad when I have to tell my grandkids they can't read my radio related e-mails with me any more. If this continues I will be looking elsewhere for my antenna information.

There is nothing you can do any better than is already being done.

If you were moderator, all you can do is delete the spam AFTER the damage has been done, and then zap the person who sent the spam. That is what has already happened here. (Yes, there are moderators.) The problem is they just sign up again and spam the group again, and you are powerless until after each one of them happens.

Other groups (including the [LoopSkyWire] group) give the moderators the ability to block new members from posting. This one doesn't. We're stuck with how this one works. Sorry.

Actually, that is not true, I own a few groups and have them set to "moderated", hence the term moderator. That way a message HAS to be approved before going out... You must not have much message board moderation / user experience?

The simple answer is we can't. Like I stated earlier, the original group owner went AWOL and didn't give the current moderators the ability to make any changes. Every time we get new members here this gets rehashed over and over again, if you search the archives you will see this is so.

What you seem to be missing (and it has been said here many times already), is that THIS group, doesn't give the moderators that capability. THIS group has no "owner", sort of like the "chief moderator", who controls what powers the other moderators can have. The moderators of THIS group do not have the capability of setting people to "moderated" status. It cannot be changed.

That is why the moderator of this group also moderates the OTHER Skywires Yahoogroup, also known as [LoopSkyWire]. On that group, like on almost every other Yahoogroup, the moderators DO have the ability to do what you say. Unlike this group, it is spam-free.

And if you had paid attention over the last two years, you would have seen that this issue has been discussed already, with explanations given about why the moderators can't stop the spam before it happens.

It's not a problem that you didn't. But it is a bit surprising that it had to be explained many times in the last few days alone.

> Sheesh, what is with all the attitude ...

What attitude???

The only attitude I see, is yours.

The "rehashing" apparently gets you upset. I don't see that it made Dave upset. He was just pointing you to where you could see it being repeated over and over. That is just something we, as members of this group, need to put up with whenever it happens. We all know it is a fact of life in this group. Dave doesn't seem to get upset about repeating it a few times a year.

No need to! There is already one. It is called [LoopSkyWire] and you can find it by going to:

http://groups.yahoo.com/group/LoopSkywire

It was created two years ago (its anniversary is almost here), and if you noticed in the current thread, one of its moderators is also a moderator of this group, and pointed us to it twice in the last few days.

Sending 2 emails in a row with quotes sure seems like you have some kind of problem? If a simple question is too stressful, like I said, get another hobby and take a chill pill dude, man is the virtual air thick in here. I was NOT trying to start a flame, but I will take responsibility since I asked an innocent question and "got my head bitten off".

I was just making a valid point and was next going to ask if anyone knew the owner, his/her callsign/email and maybe could get access to change some things.

I found another group away from yahoo and google groups, so I will bug you gentlemen (and ladies) no longer since a sincere question gets so many feathers ruffled? I have NEVER run into such hostility from such a simple and valid question in my life. I have had major debates that were more civil than this in many groups!

Sorry I asked a simple, valid question, and maybe I did not see the other similar questions/answers as sometimes "good" emails go to the "spam box" and are deleted without me ever seeing them.

I understand the bad weather may have folks down with "cabin fever", so I hold no grudges and just ask the same of you please?

Sincerely,

Walter

Hey all,
  Hope to have my 80m wire in the air soon. Part of it will have to skirt a 25’ and a 75’ edge of my 25 X 75 shop (borders property lines) and it may be hard to get it more than 10’ over the metal roof. I plan to feed at the opposite end where the loop is away from the metal roof shop. Any feedback or experience that may help or save me some grief?
   I'm kinda’ new to SkyWires but I have set up Yahoo Groups for special events. Some access can be open so no one has to approve each person. When the group is set up were a moderator has to approve each applicant and a few core group members have the moderator information then any one of them can serve as moderator (this is how I set up the Blackberry Festival Group), When the moderator does not share the log in moderator info or if one of the folks with the moderator access changes the password and does not inform the others of the change then the group is stuck with what ever and cannot make any changes.
   Yea, I know, this was not about wires in the air.
Abe

Hey,
  I’m new to SkyWires and hope to be in Loop SkyWires soon. Why does any one have to “own” it? Does the group belong to a person or the members? We are all HAMs, I hope, or at least share a desire to improve radio communications (part of our mission I try to make sure new techs understand) and should share a common integrity not found with many groups. A moderator should be able to find a few trusted friends to share the moderator login and password info with to help with the screening (yea, I know it is hard to get any one to step up but it sure makes life easier when thy do).
Abe
P.S. When every Board member has moderator access and can call one of the other Board members to get the info when they forget every thing goes well and smooth for the group.

Actually, that is not true, I own a few groups and have them set to "moderated", hence the term moderator. That way a message HAS to be approved before going out... You must not have much message board moderation / user experience?

There is nothing you can do any better than is already being done.

If you were moderator, all you can do is delete the spam AFTER the damage has been done, and then zap the person who sent the spam. That is what has already happened here. (Yes, there are moderators.) The problem is they just sign up again and spam the group again, and you are powerless until after each one of them happens.

Other groups (including the [LoopSkyWire] group) give the moderators the ability to block new members from posting. This one doesn't. We're stuck with how this one works. Sorry.

If you plan to feed it with ladderline just make a bridge near your shop that can be opened . now your 80m loop is a (bent) topbanddipole

Just an idea for anybody that can not build a megaloop (160m) . make a bridge that can be opened and you have 2 antennas in one

An: SkyWires@yahoogroups.com
Betreff: Re: [SkyWires] message content

Hey all,

Hope to have my 80m wire in the air soon. Part of it will have to skirt a 25' and a 75' edge of my 25 X 75 shop (borders property lines) and it may be hard to get it more than 10' over the metal roof. I plan to feed at the opposite end where the loop is away from the metal roof shop. Any feedback or experience that may help or save me some grief?

I'm kinda' new to SkyWires but I have set up Yahoo Groups for special events. Some access can be open so no one has to approve each person. When the group is set up were a moderator has to approve each applicant and a few core group members have the moderator information then any one of them can serve as moderator (this is how I set up the Blackberry Festival Group), When the moderator does not share the log in moderator info or if one of the folks with the moderator access changes the password and does not inform the others of the change then the group is stuck with what ever and cannot make any changes.

Yea, I know, this was not about wires in the air.

And if you had paid attention over the last two years, you would have seen that this issue has been discussed already, with explanations given about why the moderators can't stop the spam before it happens.

It's not a problem that you didn't. But it is a bit surprising that it had to be explained many times in the last few days alone.

> Sheesh, what is with all the attitude ...

What attitude???

The only attitude I see, is yours.
(Looks like you are all in a knot?).

The "rehashing" apparently gets you upset. I don't see that it made Dave upset. He was just pointing you to where you could see it being repeated over and over. That is just something we, as members of this group, need to put up with whenever it happens. We all know it is a fact of life in this group. Dave doesn't seem to get upset about repeating it a few times a year.

Andy

Sending 2 emails in a row with quotes sure seems like you have some kind of problem? If a simple question is too stressful, like I said, get another hobby and take a chill pill dude, man is the virtual air thick in here. I was NOT trying to start a flame, but I will take responsibility since I asked an innocent question and "got my head bitten off".

I was just making a valid point and was next going to ask if anyone knew the owner, his/her callsign/email and maybe could get access to change some things.

I found another group away from yahoo and google groups, so I will bug you gentlemen (and ladies) no longer since a sincere question gets so many feathers ruffled? I have NEVER run into such hostility from such a simple and valid question in my life. I have had major debates that were more civil than this in many groups!

Sorry I asked a simple, valid question, and maybe I did not see the other similar questions/answers as sometimes "good" emails go to the "spam box" and are deleted without me ever seeing them.

I understand the bad weather may have folks down with "cabin fever", so I hold no grudges and just ask the same of you please?

Sincerely,

Walter

> one have to “own” it?

Because that is how all Yahoo!groups work. Every Yahoogroup has one Owner and optionally one or more other Moderators. It is inherent to the Yahoogroups structure.

The Owner has somewhat more privileges than the other Moderators, and can restrict what privileges the other Moderators have. That is unfortunately the problem with this group; the Owner restricted the other Moderators' privileges, and has disappeared, leaving them powerless to really fix the spam problem. Yahoo's policy has been one of "hands-off", rarely ever intervening for an Owner even when he/she disappears from the face of the earth.

This group has three Moderators in addition to the missing Owner. I happen to think they are doing a very good job, given the fact that their hands are tied.

3697. Re: Balun or not to Balun

Yahoo group: SkyWires
Date: 2010-03-21 16:43:17 UTC
From: Aaron
Topic: 3608 Message: 3697

So I thought I would update this with some new findings. I don't need an external tuner anymore (well almost)!!

I recently bought a Elecraft 1:1/4:1 balun kit just to build and play around with. Last night I decided to bypass my SGC and see what would happen with the 4:1. To my amazement I found that I had acceptable standing wave almost on every band for the 60 & 40 meters.

160 is 1.9:1 at 1.800 with my lowest of 1.4:1 at 1.893 then up to 2.7:1 up towards 2.000

80 Meters is a high towards the lower end but is acceptable from 3.800 to 4.000

60 Seems to be about 3:1

40 is about 2.7:1 around 7.000 but stays consistently 3:1 across the band

30 is about 1.6:1 across the band

20 is about 1.6:1 at 14:200 with no higher than 2:1 on the band edges.

17 is no higher than 1.3:1 at the top of the band

15 is 1.3:1 to 1.6:1

12 is about 2:1

10 is 1.7:1 and dips to 1.4:1 at 28.300, 2:1 at 29.000 and no higher that 2.2:1 at the the high end of the band.

6 is 1.5:1 at 50.000 and dips to 1.2:1 at 50.500 then peaks to 1.9:1 at 51.500 and then dips back down to 1.2:1 at 52.500 and not greater than 2:1 the rest of the way up.

I am truly amazed and will start playing around with the ladder line length to see if I can shift 40 in range a little better. My internal tuner on the FT-950 (which can't tune much) had no issues picking up the slack where the standing wave was higher desired.

At this point I am not sure the external tuner out near the feed point is really needed anymore. I am not seeing any high ratios that would warrant the need for the extra equipment now and looks like I have accidently got this loop close to being right with falling into the harmonic ranges for multiband uses thanks to the 4:1. I did not have these results when I had the loop direct fed with coax when it first went up.

So to answer my own question... yes to the the 4:1 balun :)

Topic: 3699 Message: 3699

i have been useing a 100ft long wire, fed by 15ft of 300 ohm ladder line, with my modified realistic dx394 shortwave receiver. it is hooked to the corner of the porch 15ft up and rises up to about 30ft in a tree. and it works pretty good but is kind of noisy i have decided to put up a triangle loop (not enough trees to do a square or circle) to see if it is quieter i will add about another 100ft to another tree up to about 40ft high then 80ft back to the porch, and feed it with 50 ohm coax again trying to get rid of noise. do i need to use a balun or an unun with the coax? or should i just feed the shield to one side of the loop and the center lead to the other side? any thoughts will be appriciated thanks steve

If you are concerned with noise .... especially noise generated closer to the listening position .... then feeding the loop directly with coax will not "shield" the receiving system from this RFI. If the coax is not properly terminated at the antenna all RFI picked up by the coax shield will be dutifully transferred to the loop and on to the radio input. You will be much better off continuing to use the 300 ohm feed line (TV type or ladder line). It will pickup less local RFI than directly connected coax.

It must be understood that in order for what is euphemistically called the "shield" of coax cable will only act as a shield if the inside is separated from the outside. This is tricky since they are connected ... e.g. one and the same at each end. So now you essentially have a 3 wire feed line .... the inside of the "shield and the center conductor being the feed line and the antenna consisting of the loop and a long wire (the outside of the shield) and the loop connected together. The loop part of the antenna nicely located away from local RFI and the long wire (the outside of the shield) courses nicely through the RFI zone! The signals from both of the antennas combine and go to the receiver input.

Now contrast this to the 300 ohm twin lead (supposedly unshielded) ..... It consists of only 2 wires .... all signals picked up by the loop will present RF voltages to the feed line which will in turn be presented to the receiver input (the receiver input must be balanced). However any signals picked up by the feed line itself will be in-phase at all points along its length .... right up to the receiver input where they are cancelled at the balanced input. At the other end of the feed line they are also cancelled as the antenna is also balanced. Voila! the 300 ohm balanced feed line is in effect shielded!

It will be much easier to have a shielded feed line if you use the 300 twin lead. Just be sure you use some kind of balun at the receiver ... which more than likely has an unbalanced antenna input. Most of the old style SW

receiver already included such a balanced input. If you do use coax feed line and you don't separate the inside from the outside then you will simply continue to have a long wire antenna with a loop on the end !!

Jim

Hi Aaron,

I think the arrangement of coax/SGC239/ladder line will work. However I suggest putting the balun on the other side of the SGC tuner e.g. where it connects to the coax line. A 1:1 current balun will do the trick e.g. wind your own with coax. That impedance point is always at a constant low impedance (50 ohm range) ... where the balun works best. The other side of the tuner, where it connects to the 450 ohm ladder line can be almost any complex impedance ... what the SGC tuner is designed to deal with .... but is very hard to deal with as far as a voltage balun is concerned. I have used a similar arrangement ... and the physical arrangement of the SGC239 is particularly easy to work in this arrangement. the frame of the tuner is kept separate from ground and is connected to one side of the parallel line. The other side of the parallel line connects to the hot output lead. Very easy to do. Put another small homemade current balun on the DC power cable. This arrangement will keep the ladder line/antenna in balance and automatically match the 50 ohm cable impedance to the complex impedance presented at the end of the ladder line (within the range of the SGC239 ... which is considerable).

The problem, as I recall, is that Walter ("exemptfromlife") has been missing from this group, and either didn't or won't grant enough privileges to the other three moderators to let them *prevent* spam before it happens. All they can do is kill it after it happens. They have been good at that; unfortunately it doesn't help those us who receive our posts in email and receive the spam before they can stop it.

Andy

Why delete it? Leave the old group here!

If you don't like the spam here, YOU can walk away from it, but don't make it so that everyone loses out by no longer being able to access the archives.

(Better yet, there are ways to recover a Yahoogroup when it gets neglected by its owner, and I think the moderators should pursue that avenue first before even considering killing the group.)

3743. TOWER FOR SALE

Yahoo group: SkyWires
Date: 2010-06-08 15:57:32 UTC
From: kg4coq
Topic: 3743 Message: 3743

Hello All,

I have for sale 4-10 ft. sections of streight and 2-9 ft. top sections of Rohn 25 tower.

Sections are in good very useable shape but some need cleaning up... (Surface rust)

Selling all $250.00. I will trade my tower for a ICOM AH-4 TUNER or something else I may need.

Pickup in Largo Florida.

Will deliver within 30 miles of Largo Florida for $25.00 more to cover fuel cost.

Selling all because can't find anyone to help me put it up.

Please email me directly or call the following phone number.

Thank you,

Don Rosselli

Gary if you use coax on your 40 meter full wave loop you will lose the multiband operation advantage of the loop. Though it may also work on 15 meters.

You may also have a hard time matching the coax directly to the feedpoint of the loop as the feedpoint impedance will be above 100 ohms.

Topic: 3751 Message: 3751

I presently have a 540' loop with a configuration between a square and a rectangle with the far side shorter than the nearer feed point side. I use 450 Ohm ladder line to a Johnson Matchbox in the shack. Starting at 32 feet in 1986, the antenna height is now 44 feet on average as the trees grew over the years. All ropes are on pulleys with brick weights with pulleys or bungee cords on the far end of the pulley rope pulled over the tree. They have survived 75 MPH winds. Observations: Play the corners and watch out for nulls! The antenna is extremely good off the far corner from the feed line on 40 and 20 (the Middle East for me). I have worked India on 40 as well as the deep-in-Asia ..."stan" countries with 400 watts. Off the sides on 40 my 4-element vertical wire array is 1 S-unit better than the loop. There are nulls on 15 and 10 that are frustrating, but the antenna is a pile-up buster on 17 in most all directions. The loop equals my 5/8 inverted L on 80 but is slightly poorer than my 3/8 inverted L on 160. The more radials I added to these L antennas in the middle of the loop the better the loop plays. Downward shooting RF may be reflected back into the loop wire and radiated ??? My newest experiment is a 15/12 Lazy H. After all that work to get the H up, the loop usually outperforms it in the favored H direction. Fellow club members ask, "why no beam?" One can not see my black wire loop from the streets next to my corner house. No neighbor issues and 250 countries and counting. Best antenna I have ever used, including an A3 beam at 40'.

Hello,
For a loop 1005/Mhz = feet . Ladder line is best for multi-band operation.
If U will only be using one band coax is fine.

3761. multiple resonant monoband loops vs one loop and a tuner

Yahoo group: SkyWires
Date: 2010-10-26 13:39:06 UTC
From: bas_tad
Topic: 3761 Message: 3761

Has anyone done any study on whether a tuned monoband loop performs better on its band than a multi-octave or random loop will perform on that particular band?

I've been using monoband loops on 20 and 17 meters and am planning on putting up a 40m loop. I have a handful of 100 ohm baluns and they seem to work great as long as I don't put the loop up too high.

Problem is now I've run out of room to run cables hihi. I'm seriously trying to decide between a remote antenna switch and a large loop, open wire feeder and a tuner in the shack.

Aren't large loops directional at multiple octaves of the operating frequency? How much so?

My loops have mostly been 'sloping' loops - triangle, fed at the top, with the loop itself acting as part of the guy system for the push up pole that is holding it up. (I like to say my antenna is holding up the pole that is holding up my antenna, but I digress ...) This obviously won't work for 40 and 160 meters.

Thoughts? References to any published material? I can only be anal about this once, hihi then they stay up until nature takes 'em down!

Thanks
Tracy N4LGH

> what works best Ladder line or 4:1 balun with coax

I always use a 2:1 balun (1:2) for coax fed loops. The resonant impedance of a loop is near 100 ohms at most heights we would put them.

I'm not sure what the feedpoint impedances are at other than resonant frequencies, but if you use a 4:1 balun make sure it has a beefy Powdered Iron core instead of ferrite as you will have huge RF voltages present at the balun during tuning; if you run power you can actually damage a ferrite balun if the impedances are way off.

I'm struggling with the same question, but I've destroyed a ferrite balun tuning 500 watts into a 40 meter loop on 80 meters. I'll never do that again!

From: Siegfried Jackstien
Topic: 3761 Message: 3763

I have very good results with a ladderline fed topbandloop

Maybe next will be a 2 wl loop for topband

Surely you have a cloverleaf pattern on the higher bands with points of lower signal between the biggain lobes

But where the lobes go there is much gain on the higher bands . and if you can model your antenna with mmana or eznec you see where your max gain goes

I did that before erecting the loop and made the direction and the lengths of the sides that most gain on 40 is to southwest (lp to vk and zl)

And that worked for me

Your situation may be different

But as a multibandantenna I would allwas erect a ladderline fed loop or a similar fed dipole

I had both and what I found out is that loop receives better (lower noise level)

So try it out

3764. Balun 1 to 1 or 4 to 1

Yahoo group: SkyWires
Date: 2010-10-30 14:28:52 UTC
From: Joe
Topic: 3764 Message: 3764

Evening Gang,

I'm wondering here is the situation..

I have a random loop. It's all horizontally laid out strung between four trees.

It's random length, just what would fit as large as possible. It's probably resonant as a full wave loop somewhere near the 5 MHz band, (that i do not operate in.)

It is about 40 feet above the ground. Fed in one corner with some TV twin lead about 30 feet or so. then the remainder is some 50 ohm coax again ohhh 40 feet or so.

Now the question is here, I have a 1 to 1 balun,, and a 4 to 1 balun. What one would be the best to put of course where the coax to twin lead spot is.

Wat one would be the most efficient? By the way I will want to use this antenna on all bands 160 thru 10 meters.

Joe-- Your loop is not random, it is a definite length. You should measure it, to know. "Random"ness is a description of our state of Knowledge. In regard to an antenna, it is only random until you make it. When a post on a tuner is labeled "Random" that means, roughly, "Whatever" it is hooked to. Until you have measured the characteristics of the antenna, it is hard to answer the questions about the Baluns. The devices you refer to as "1:1" and "4:1" are really "Impedance transformers".
The TV Twin Lead has a "Characteristic Impedance" of 300 Ohms and is a "Balanced" line. The Coax is an "Unbalanced" line and has a Characteristic Impedance of 50 Ohms.
The major advantage of Twin Lead over Coax, is that there is less loss when the line is fed with a signal that has an Impedance that does not match the line.

So best would be ladderline to shack and symmetrical tuner in shack

Second best ladderline to shack and single ended tuner with 1:4 balun on the outputside

Third is coax to antenna and balun in the air (or some feet down and ladderline for the rest (what I call rubbish for multiband)

I equal this opinion.

Ladderline gives you the best flexibility and in combination with a
symmetrical tuner the highest efficiency, when you want to use your loop
for more than one frequencyband.

When you want to use your loop for only one frequencyband the best thing
to do is to construct a one-wavelength sized loop with 1:2 balun and coax.

My loop is about 400 feet long and I use this antenna for all bands 160
and 10 meters. With ladderline and symmetrical antennatuner. Works GREAT!!

List--

Several people have made reference to a "Balanced Tuner" in this thread.

I (very much!) would like to know which tuners they mean.

In the situation described (ie, ladder line to rig) There MUST be a transition from Balanced (Ladder line) to Unbalanced (Rig input). Where this is done makes a difference.

I wish someone using this setup would describe it and identify the Tuner.

Thanks--Bill--W4BSG

From: Alan Wilson
Topic: 3764 Message: 3776

You can find a used johnson matchbox for around 100 bucks or so. I've had one and did a comparison on using one without 4to1 balun as opposed to using a standard mfj tuner with a 4to1 built in and never saw a difference in receive or transmit signal. So, just try what you can with what you have. I know I'll catch heck from you purists out there but the results speak for themselves. I sold the matchbox and just use a 4to1 and about 10ft of rgx through the wall to my old mfj tuner and I have one of the loudest signals around western montana...73 and gud luck, Alan

There is some very good reading on DX Engineering website
around baluns, tuners and balanced line.

Sigi if you have the room for a single turn 2 wl long loop on 160 meters you will see the takeoff angle of the highest current drop from 90 deg. straight up down to a 45 deg. angle that will allow you to work some DX.

3785. 80 to 160

Yahoo group: SkyWires
Date: 2010-11-11 03:28:25 UTC
From: Richard Schmuke
Topic: 3785 Message: 3785

I put up a 80M □size□ loop and used a 4:1 balun, feed with RG-8, works all bands 10 thru 40. It was a great antenna. I added some more wire to bring it up to 160 size but it does not cover the bands like it did when smaller. It has been trimmed to lowest SWR in 20m band. 80M size was 1.1:1 in the middle of 20M band , at 160m size the best I can get on 20M is 1.8:1with a MFJ-259B. 15M, and above are all out of range for my internal tuner. Would the antenna change impedance when I doubled the length?? What am I missing. I know the 80M loop would have a impedance of 100 ohms and worked fine with the 4:1 balun. I am not seeing any good spots at resonance like I did on the shorter antenna, I get dips but not low SWR for a solid state rig.

Hi all,
I,m using a 82 meter delta-loop.
Knowing the impedance is 100 ohms, I have build a 2:1 balun to get the 50 ohms imp.
The loop works fine on all bands (10 to 80) with minor adjusting for the internal tuner in my IC-746.

Palle,
The loop impedance will only be around 100 ohms on the 80 mtr band. I think a 4:1 balun might be a better overall pick.

Rich,
U need to adjust the loop length by a few feet at most. Measure the VSWR at the top and bottom of the 20 mtr band without using any antenna tuner. This will tell U if U need to make the loop a little longer or a little shorter.

Dr. Ace, I did check and adjust but for some reason I could not get the 160 size as close as I was hoping for on 20 and the other band were nowhere close. It was sort of a sq and one leg dropped too low and was close to a line of cedar trees Checking was done without any tuner and a MFJ 259B. I tried my old 4:1 voltage balun , a 2:1 voltage balun and my 4:1 current Gunanella balun, made with two separate cores on ferrite rods. All baluns are homemade and checked on the bench first. I took down the 160 size and reinstalled it as a 80M size delta , current balun, tweaked to the middle of the 20M phone band. The section of the band where I work (SSB) is 1.3:1 at the low end and 1.2:1 at 14.300 MHz , resonate at 14.240@ 1.0:1. 15 and 40 are also well within range and the tuner will take of the band edges. I was looking for a little gain on 20 without a separate tower, rotor and beam. I am well pleased with the loop . The only reason I changed to the larger was looking for better. I will stick with the loop I have now.

This helps to keep me out of the bars and chasing the young girls.

Rich , KDØZZ

Hi Guys

Im new to all this CB radio stuff, So im looking for a cheap-ish CB radio & all the bits I need for my recovery truck. So I can keep up with the motoway traffic reports & possibly make some new friends around the UK on my travels, So if anyone can help i`m happy to travel to collect the set up I need as i`m based in Sutton Brigde area PE12 near Peterbrough.

I can be contacted on 07787-872343 text me & I will be more than happy to call you back.

Many Thanks for all & any help

Regards Paul

3796. 11M Antron 99 on 10M

Yahoo group: SkyWires
Date: 2011-01-02 19:27:23 UTC
From: ke6vhm
Topic: 3796 Message: 3796

Greetings and Happy New Year

I have been given a "Antron 99" 11M antenna in good shape and FREE. I was wondering what the deal is with NO counterpoise radials. I was given no literature on this antenna. The guy that gave it to me used it on 11M and never had any counterpoise. Do I need to put on a radial system or not? I do know i will have to cut for resonance on 10M

Thanks in advance
73 de Frank

Antron99 can be tuned to 10m ... you do not need to cut
As far as I know....
It is an endfed antenna with stepup transformer coil at the base
that coil has a capacitive tuning ring over it
you can ad radials ... but it will not help much
if you just wanna use it on 10m ... okay go for it ... but there are better
"cb" antennas that can be used on 10

I've used CB antennae on 10, 11, 12, and 15, but the farther you go from the frequency it was cut for, the less efficient it will be, and the more the RF from the radio will be used to heat the components in your tuner instead of being radiated.

3800. window-to-window loop.

Yahoo group: SkyWires
Date: 2011-01-04 16:46:18 UTC
From: Steve
Topic: 3800 Message: 3800

I want to construct a random-length loop in the trees in my backyard, and start/end it at two thumb screws in a sheet of plexiglass in the window. On the other side will be a balun of some kind and coax to the tuner. I will use ~ 200 ft. or so of wire.

Will this work? The loop will be distorted based on which limbs I can get it over, but it will not double back on itself.

Thanks,

Steve

Topic: 3800 Message: 3801

It will work, will depend on height as to the angle of takeoff, length as to which bands will load, and may or may not need a balun, depending on how you feed it. With ladderline or twinlead and a decent tuner, it will load on multiple bands, but efficiency is a try-and-see affair because of height and length.

If you want to monoband it, coax will work, and some cut-and-try with a 4:1 balun will likely work (200 ohm impedance theoretically).

It will work , a loop does not have to be a exact shape. If you used about 140' or 280' you can trim it in and not even need a tuner. Around 140' give you a good 40M loop. I have a 80m loop and it works 40 thru 10 without need for a tuner. For 80 it needs a 2:1 balun and 40 thru 10 I use a homemade 4:1 balun. You can lay out the wire then use monofilament fishing line to support it to the trees.

Subject: [SkyWires] window-to-window loop.

I want to construct a random-length loop in the trees in my backyard, and start/end it at two thumb screws in a sheet of plexiglass in the window. On the other side will be a balun of some kind and coax to the tuner. I will use ~ 200 ft. or so of wire.

Will this work? The loop will be distorted based on which limbs I can get it over, but it will not double back on itself.

Thanks,

Steve

Steve,
Yes, It will work and should resonate around 5 Mhz.

Thanks, guys, for responding to my loop question. One more:

Should I point it perpendicular to the ground, or parallel? I want it for DX only, no NVIS, etc.

From: perryc
Topic: 3807 Message: 3807

Hi all. New to the group.
I presently have up a 220 ft g5rv dipole, at 35 ft
works good but it's very noisy.
I am thinking of building a full wave 160 meter loop.
Won't be able to get it more then 30 feet up.
Any ideas info about static or voltage coming in from being in the air.

3809. Feed the Loop

Yahoo group: SkyWires
Date: 2011-01-26 20:57:52 UTC
From: Richard Schmuke
Topic: 3807 Message: 3809

I have a approximately 80M delta loop up, patterned after M0MCX mega loop. In 2009 I put it up with a 4:1 current balun and RG-8, adjusted the loop to best SWR on 20M. It work great on 20 I also use it on 40 and FB there. In 2010 I increased it to a 160 size but never could get SWR down. I went back to 80M size. I don't think I will ever work 160 but I would like to do 75 phone now and then during a contest. I run 100 to 500W SSB. My question is feeding my 80/75 loop and use it on 75,40 and 20.

#1 Remove the 4:1 current balun and RG-8

#2 Add how much 450 ohm ladder line, does length make a difference??

#3 Add a 1:1 current balun and short (2ft) run of RG-8 to my tuner (MFJ-962D) ??

#4 Or I should do what???

3810. AW: [SkyWires] Feed the Loop

Yahoo group: SkyWires
Date: 2011-01-27 11:46:02 UTC
From: Siegfried Jackstien
Topic: 3807 Message: 3810

Hi rich
Lenght of ladderline does make difference what load is on the shackside ...
I have a 160 loop up here ... but in wavelengths it is very close to ground
for the lower band(s) ... so what I did is I use about 20m from feedingpoint
to shack on 80 and ad another 20m to work on 160 (added length is in attic
in a zig zag circle) ... in the 2 lower band the ladderline transforms the
low impedance (close to ground) to higher impedance ... so now I can use a
1:9 balun with a low swr ...
On the higher bands impedance goes up ... so ladderline is almost matched
and there is no transformation
On the 2 lower bands I use transforming of the ladderline (resonant line)
and on the higher bands it is a matched line (nearly)

What impedance you have on what band depends on high is your antenna
If you have one of the higher bands that give you bad results in swr you
could test to shorten the loop and make the ladderline longer or vice versa
...
That would let the lower bands on the same spot but could change the
impedance on a higher band ... lots of try and errors :-)
Results in impedance and lobes changes also if you feed it at one side or in
a corner
My setup is feeding in a corner cause you have then no slack by the
feedingline and I tried both feedings and feeding in the edge gave me better
results for going multiband ...

Problem with feeding a loop is that on fundamental it has low impedance and
on the higher bands the impedance goes up ...
With testing different length(s) of ladderline I could find a solution that
gave me 9 bands with low swr without needing a tuner
No tuner needed ... no tuner losses ... :-)
I had some shorter window-line lengths that were left over from several
fielddays ... and so with that I could test different feedingpoints and
baluns ... but your setup could be a bit different ... so better you try it
out ....
Dg9bfc
Sigi
Ps if you make a relay (a gooood one) in the opposite wire you can use your
80m loop on topband as bent dipole .... better than nothing on 160 but the
bigger one is better :-)

3811. Big loop in a little space - Possible?????

Yahoo group: SkyWires
Date: 2011-01-28 10:18:39 UTC
From: Madhukar KR
Topic: 3811 Message: 3811

I have been following the group for some time now and find most of the posts are for BIG size loops for all bands. I Live in an urban area Bangalore in South India. There will be no problem putting up an antenna - as long as it stays withing the periphery of the property. I am keen on putting up an antenna for 80m-10m. The only possibility I see is for a Long Wire. But the dimension is 8mts x 6mts - (25' x 19'). So the Maximum I will be able to run will be about 100 Ft - including a length up one of the poles :)
My idea is to loose wind the balance 40 ft (rough calculation of about 140' for a 1/2 wave on 80m approx.) on one or two lengths of 2" or 4" PVC pipe on the longer sides.
My Questions to the group
1. Will the antenna work?
2. If it will, What will be the limitations?
3. Will it tune across the bands? - I have a MFJ 901B Antenna Tuner.

Looking for advice and possible solution.

I have a 140 foot horizontal loop
<http://www.qsl.net/kp4md/kp4mdnec2.htm> (full wave on 40m) and a base loaded 6 foot screwdriver vertical that is tunable from 80-10m. I can transmit on 80 and 60m with either antenna, but the vertical is the better radiator there. The loop's transmitting efficiency is especially poor on 160 and 80 m. The loop gives superior signal to noise ratio when receiving on 160, 80 and 60m. I am also in an urban area where the local noise is primarily vertically polarized.

3816. LARGE vertical loop

Yahoo group: SkyWires
Date: 2011-02-05 21:50:17 UTC
From: Brian
Topic: 3816 Message: 3816

Hello All,

Well, as Yogi Berra said "Nostalgia ain't what it used to be". In spite of that, I've been bitten by the ham radio bug again after an absence of over 50 years. A couple of ham buddies from high school looked me up on the web, and one offered to set me up with his spare equipment if I wanted to renew my license.

All of which has gotten me thinking about antennas for my tree filled location here in redwood country on California's north coast. There are two tall trees, with none in between, that are separated by perhaps 200 feet that would lend themselves to supporting a LARGE vertical loop. It could be a rectangle as much as 175 feet long by 50 or more feet tall, and 10 feet off the ground.

My question is what would be an optimum use of all this space? I'm interested in all the bands from 80 through 10 meters, and will have a Harvey Wells Z Match antenna tuner for matching things up. Is there any advantage in making it as large as possible? Any trade-offs?

Thanks a bunch,

Brian Burns□the once and future K6UCD

For multiband use you can just use a horizontal loop or a horizontal dipole
A vertical loop is only for one or 2 bands ... so think of building a dipole
or a horizontal loop with the 2 trees and a third support
Okay you would need a third pole tree mast .. whatever
But a vertical will not work multiband

Hello Andy

~ Why is it that a vertical loop doesn't work multiband? ~

Here is an excellent link for general loop info in case you haven't run across it:

http://mysite.verizon.net/ka1fsb/loopants.html#shapesize

The general discussion of loop antennas at the link above makes no mention of a vertical loop's working only on one or two bands.

And here is an interesting quote from his article:

"It should be noted that horizontal loops can only transmit in the horizontal plane. And that vertical loops can be fed in such a way as to either effect horizontal polarization or vertical polarization depending on how (i.e., where) they are fed. If a vertically oriented antenna is fed at either the bottom or the top, the polarization will be horizontal; if fed on the side or bottom corner, it will be vertical. If you are going to the trouble of putting up a large vertical loop, be sure to feed it to take advantage of the low angle of radiation mentioned above!"

He is recommending feeding it at the side or corner for vertical polarization-- "to take advantage of the low angle of radiation mentioned above!"

Another aspect of the vertical loop:

"Large vertical loops that are 1 wavelength in circumference have a low angle take off and do well for DX only on the fundamental frequency. A 270' vert. loop would do fine on 80m but on harmonics the angle would increase which is normally the opposite of what you would want."

So, my question is, does feeding a vertical loop at the top or bottom for horizontal polarization make for the desirable lower take off angles on the higher bands as with a horizontal loop?

I'm going to all this trouble because my antenna site is ideal for a very large vertical loop, and is a
lousy site for a horizontal one.

I would ask KA1FSB directly if I had an email for him. Anybody know it, or how to find it? I tried QRZ.

Cheers,

Brian

> http://mysite.verizon.net/ka1fsb/loopants.html#shapesize

I've seen that website, many moons ago.

While he has some good information, I do take issue with parts of it.

> "It should be noted that horizontal loops can only transmit in the
> horizontal plane.

Well, that's not true. Full wave horizontal loops make excellent
cloud-burners (NVIS antennas), with little signal transmitted in the
horizontal plane.

Checking the article, I see that he was talking about horizontal
polarization (i.e., the polarization is in the horizontal plane),
not that it radiates only in the horizontal plane.

> He is recommending feeding it at the side or corner for vertical
> polarization-- "to take advantage of the low angle of radiation
> mentioned above!"

I don't follow that. Vertical polarization has little to do with
angle of radiation. The antenna itself can have low angle radiation
whether horizontally or vertically polarized (though the polarization
does interact with the earth and alter both its pattern and
polarization somewhat).

> So, my question is, does feeding a vertical loop at the top or bottom for
> horizontal polarization make for the desirable lower take off angles on the
> higher bands as with a horizontal loop?

I don't believe the feed point (and polarization) has a very great
effect on the radiation pattern, i.e., where the most signal goes.

On harmonics, the pattern of a loop tends to flatten out towards the
plane of the loop. In the limit it approaches the plane of the loop,
I think in all directions around the loop (if the loop itself has any
resemblance toround; hexagon, maybe even a square). This doesn't
depend on where the loop is fed. Yes, you'll get little lobes going
this way and that, but overall it is supposed to be fairly uniform
around the circumference of the loop. He says elsewhere that a
horizontal loop is omni-directional.

I realize reality may differ from this, so don't necessarily take my word on it.

> I would ask KA1FSB directly if I had an email for him. Anybody know it, or
> how to find it? I tried QRZ.

Elsewhere on his website he lists:

[email: ka1fsb@...]

(In case Yahoo hides that, it's his callsign at ATT dot net.)

Regards,
Andy

(This is in reference to three recent posts)
The article by KA1FSB is pretty misleading. He seems to not realize where "gain" comes from, and has some other shortcomings. There is little technical or theoretical content. A better understanding can be reached from getting one of the free modeling programs and trying different types. Always model above real ground, because gain comes from distortion and reflection.

From: Richard Schmuke
Topic: 3822 Message: 3822

I have had some great responses from people all over about a good signal on 40 & 20 from my 80m Delta loop with a 4:1 balun so I want to keep the loop but the SWR is not so hot on some of the other bands so thinking about ladder line and no coax SWR problems.
The old model voltage balun showed better SWR reading than the new current one on the antenna. The bench test was the other way , better with the new current, so that means ---DUH--?? Did the voltage balun hide a problem.
With ladder line I could work 80 on my 80m loop now it is 40 thru 10. Any opinions on changing from RG-8 coax feed to 450ohm ladder line?

☐Rich...

Although I don't use one, a voice module is available for the 590 for $65 as described at http://universal-radio.com/catalog/hamhf/29490590.html .

Thank you for your reply. I have seen the website before of you beautiful place. I must complement you on how well behaved "Michael" is, my "Bagira" always steps on the keyboard at the wrong time or wants rub a knob the wrong way.

I do have a quick question about your Kenwood 590. Do you have a audio record board and can it be used to send your call or other things?

I am thinking about a replacement for my 450SAT.

Subject: [SkyWires] 80M loop

I have had some great responses from people all over about a good signal on 40 & 20 from my 80m Delta loop with a 4:1 balun so I want to keep the loop but the SWR is not so hot on some of the other bands so thinking about ladder line and no coax SWR problems.
The old model voltage balun showed better SWR reading than the new current one on the antenna. The bench test was the other way , better with the new current, so that means ---DUH--?? Did the voltage balun hide a problem.
With ladder line I could work 80 on my 80m loop now it is 40 thru 10. Any opinions on changing from RG-8 coax feed to 450ohm ladder line?

Rich , KDØZZ

From: Brian Burns
Topic: 3821 Message: 3826

Hello Andy and Bill,

Well, this is so much like my "real life" job of doing the acoustic voicing of the classical guitars that I build. A function of so many variables that first you build it then you adjust it (:->).

So I think that I'll put up the largest vertical loop that my site will allow, and start dinking with it. Can't you see me changing bands by running outside in the rain to flip a bunch of knife switches?

Cheers,

Brian

A friend from me wanted to work 160 bu could only errect a 80m loop ...
The trick now was he changed the feedingpoint of his loop from the roof to the otherside (far away in the backyard) ...
Now where the feedingpoint was (close to shack) he installed a knife switch
When working 160 he opened it and had a "bent" dipole for 160 made from his 80m loop
Do NOT use a trap at this point (tooo much loss)
If you use a relay use one for HIGH voltage (best c2 in a row)

3837. texas loop idea

Yahoo group: SkyWires
Date: 2011-02-15 07:22:19 UTC
From: Tom
Topic: 3837 Message: 3837

Good morning men, question for the group at large. Has anyone modeled a loop built in a cage configuration? I made a quick drawing on paper and will try to upload to the files section. A quick summary, 4 towers at 40 feet to support the wire. Cage diameter could be anywhere from 6 inches to 12 inches. I see in the ARRL book, this arrangement is good for 40 meters using a single wire, but with a larger diamter cage this should lower the frequency a good bit, I just can't figure out how much.
Antenna will be near over sandy type soil on the Gulf Coast of Texas.

I've thought of making a loop curtain configured like a normal loop but using 4ft or 6ft wire fence for the loop to expand coverage on 75m (I like running without a tuner into resonate wires when I can). This would go up in the Livingston, Texas area where there is about 4ft of sand and a few inches of water on red clay.

3840. mfj-974h need a little help for loop

Yahoo group: SkyWires
Date: 2011-02-16 04:27:36 UTC
From: ke5htb
Topic: 3840 Message: 3840

Hello All I am new to this group and have read back into the grpoup to find a answer also. I have to say I got red eye from reading so I stopped and figured I will ask.

I just purchased a used mfj-974H balanced tuner and I can NOT get it to tune any band or do anything on my 80m loop and 450 ohm feed line.

NOW reading more tonight I will try longer feed line as mine is pretty short but I feel I should be able to see some deflections of some kind
with what I am using now. I went back to my dentron super tuner and it works ok. I just wanted to see the if there is any real differences in using the balanced tuner with my loop and to learn a little more about the different tuner and then I will probably sell this 1 after I play enough. I am planning on building 1 for myself to replace this and I have most of the parts now but not all yet. So I got this to hold me over till I can get my other built.

I can not tune any band any settings any inductor settings. it shows 1.5 swr and 10 watts and thats only thing close is the 10watts i tuned with. I tried every inductor letter 1 at a time and turned the dials slowly to see any changes at all on my meters on the radio and tuner- none at all.

I like to know if I need to add a ground wire from the bottom conection to the ground lug on this tuner like I did on my dentron tuner ? I dont see why I should but I am lost and I dont want to damage anything as I am disabled and cant afford to fix a radio or anything else.

OH radio is a 570dg all barefoot no amps just a basic setup. Ladder line all the way into tuner no chokes nothing in line on feedline at all. nothing special just aprox 270+- wire up at 30' and direct to tuner with 450 ohm. I believe and will say aprox 35to 30 ft ladder line max used to tuner.

Looking for suggestions and any help as I am going nuts and hope I didnt justy throw away money on a bad tuner now. be 2nd bad online deal in 8 years buying online. this 1 will hurt more cause guy has already said no returns at all so it is mine no matter what and looking inside of the tuner I do not see any loose wires or any of the normal MFJ missed wires or anything like that. I did notice 1 possible burn spot on the inductor switch but not a bad spot but it is there.

Guy says it worked 100% before he boxed it and shipped it to me. pack job was ok could have been better but it was ok. tuner did move around some inside. I do get some meter movements and light does still work so I dont think it was beat up in mail much or damaged that way.

HELP PLEASE what amd I maybe doing wrong or suggest things to try before I call MFJ and spend a small fortune fixing this and loose money by not buying a new 1 to dtart with for the 100.00 more. I feel what I paid was a fair price at 125 shipped so I am happy there. tuner was in real nice shape not beat up scratched up nothing to say it was abused.

only power run thru it was 25 watts fm to see if it worked.
I run 90% digital modes due to my other tuner did not like me too much for rfi in house on 20m only. so after trying this I was real bummed out totally.

thanks in advanced for ANY AND I MEAN ANY HELP AT ALL.

TIME TO TAKE PAIN MEDS TO RELIEVE MY (oops sorry caps) bad day stress and pain levels from sitting here too long.

Sounds like your doing everthing correctly. Since the dentron works fb with it. I suspect the tuner. I've used both link coupled (johnson matchbox) and 4to1 balun to normal tuner and saw no difference on transmit or or receive signal strength I'd go with whatever fits your situation. If you had it connected properly, the new tuner should have found a sweet spot somewhere on some band so I think you got a bad tuner..Especially since the guy said we wouldn't take it back..my 2cents..73, Alan

Actually I think tuner is ok just out of range on my loop for it
to do anything, I need to add more feedline to bring the numbers
more in line for the tuner to work it seems at least.
at least this is all I have to try 1 day when I get more l;adder
line to test with or make new 600 ladder line used that. but for
now I just put my dentron super tuner back inline and let it do
its job as I have my setups. being disabled it is not so easy to
fix things outside now a days so I have to wait for some help to
get here and get wire made or find some extra 450 someplace. then
in a small town where do you find 450 to have maybe 15-20 feet
max. heck smallest they sell even seems to be 50' anymore. and I
cant do that for a month either. so It stands still untill i can
do something else.

Topic: 3842 Message: 3844

From my experience I would say your new tuner isn't working properly. If your other tuner works that tells me lots. I run a 160loop with about 50 ft of ladderline to a 4 to 1 balun. My autotuner will tune most bands just fine. I run into a problem in the lower phone band and below on 75 but can tune it with the manual tuner. I've tried the loop with both link tuner (johnson matchbox) and using a balun outside the shack and bring the coax in. My findings were no difference in xmit or rec signal strength so I so the matchbox and stay with balun and coa cause its just easier. The seller of that transmatch would make me wary. Geez no return on a tuner. If you a antenna analyzer you can play with matching the antenna also. I did that with the manual tuner. Made notes of resonant point and use them when I use the manual tuner. hope you get it figured out..73, alan

Hi OM Tom!

Here's a model of your 4 wire square cage loop using 14 gauge wires with
1 foot cage width and 36 feet to each loop side.
The loop is suspended between four 40 foot steel towers in a square over
sandy soil.
This 4nec2 <http://home.ict.nl/~arivoors/> model is uploaded to the
files section as "40m cage loop.nec" and the screen captures are in the
photos section.

[40 meter cage loop]

The SWR curve shows broad resonances near 7.5 MHz and 13.6 MHz.
Using a cage elements rather than single wire loop sides does not appear
to significantly lower the loop resonant frequency.

[40 meter cage loop SWR vs. freq.]

If nothing is loose in tuner it should be ok

Sometimes you can find bad solder joints in the mighty fine junk ...

So check if all connections in the tuner are ok

It should work well on any band with that loop

I think your are just using it wrong maybe?!?

Set caps to mid setting and turn inductance till swr drops just a bit ...
that should be right coil setting ... now with tuning the caps swr should be
well tuneable ... if not try one setting higher or lower ... but it should
absolutely work with your antenna ... other tuner works without problems so
seems as either you make a fault or tuner has a fault

Hope you find it

Ok, thanks for the picture and graphs.
Is it simple enough with your program to vary length some to move the resonance around? 7.5 and 13.6 are a bit out of bands hihi

From: kp4md
Topic: 3837 Message: 3848

In the first model I posted, even with the resonant frequency at 7.5 MHz, the SWR is less than 2:1 over the entire 40 meter band.
In this new model, each cage loop side is increased to 38 feet length. The 40 meter resonance drops to 7.2 MHz, but the 20 meter resonance drops even lower to 12.8 MHz.
I've noticed that the second harmonic resonance of any loop I've modeled or built is somewhat displaced from twice the fundamental resonance. So, I trim the loop for a compromise point between the two bands and use the antenna tuner for a best match.

I found that when I made a caged antenna before (sorry it was a vertical) that a 20M antenna is more affected by a 5" dia cage than a 40M and that is why they don't seem to be the same ratio to each other.

Rich, Kd0zz

3850. Re: [SkyWires] mfj-974h need a little help for loop

Yahoo group: SkyWires
Date: 2011-02-18 03:20:51 UTC
From: Dr.Ace Ratliff
Topic: 3840 Message: 3850

Hello Fred,
To avoid problems matching any center fed antenna with high impedance open wire lines, keep the feedline around these lengths. 80 meter antenna 34-40, 90-102 or 160-172 feet
[Avoid 66, 135, 190 ft]

As for the tuner, start with the radio on 3.995 Mhz. Check that the tuners 160 meter front panel push button is not in the 160 meter position. Set the tuner's antenna knob to 1, Inductance to F and Transmitter knob to 1. Then transmit at about 25 watts Carrier. Rotate the Transmitter and Antenna knobs for maximum forward and minimum reflected power. If you can't get a match set the tuners Inductance to E and try again, If still no match set the tuners Inductance to D and try again. Never switch the inductor while transmitting.

Good Luck and 73, Ace

OK, many thanks once again. I have a SGC 230 antenna tuner I am going to use with this loop, so the info is useful to be sure that the 230 will find a match too..this also helps me decide to feed with coax or some variation of ladder line.
regards
tom

If you use a tuner at the antenna there is absolutely no need to make it
cage style

Fair comment, but I'll try and explain why my thoughts went this way. A antenna manufactruer makes a pretty good case for his cage dipoles. I was thinking if the same efficency worked for that big dipole, why would it not work well in a loop?
Now having said that, I have not built this thing yet,I'm still trying to get a clearer view if it would be worth the extra time/expense/effort...On the model made for this, it actually looks like it will work OK, but of course following the mails here, loops do work well. I have the real estate to put one up, just trying one a step better...I hope.
regards
to all
tom

If you wanna have more gain the cage does not help
Okay it lowers resistance (but not that much)
It makes antenna wideband (not needed with a tuner)
SO I THINK IT IS WORTHLESS

Yes, 24" chicken wire or 4ft to 5ft rabbit fence. Some of us have it on hand and it is easy enough to hang in the trees.letting the fence hang down with double support at each corner would be easier but hanging the fence horizontal is doable too if that is what it takes. I don't mind puting it up and taking it down several times to get it resonate so no tuner is needed (I avoid tuners when I can). And my goal is a single wide band, a double 75 or 160 designed for 75m phone use.

3858. Loop Feed Experiments: Results

Yahoo group: SkyWires
Date: 2011-02-22 08:30:09 UTC
From: John
Topic: 3858 Message: 3858

How do your experiences relate to this:

In my backyard I have a 276 foot square loop of 18 ga. wire average height 15 feet above the ground. I fed it four ways: Coaxial, 450-ohm line, simply fed by bringing the two ends (tied around and into the two holes of an insulator) into the shack (balanced wire terminals, MFJ window panel), then using only one end of the loop connected (as in a long wire antenna) with counterpoises on every band. The feeds were fed into an MFJ Versa Tuner 2.

These are the results (from best SWR and most tunable to biggest SWR and least tunable).

1. Open-ended loop, fed like a long wire with counterpoises, but working far better than a regular long wire, as it has all the principles of the closed loop. Will even tune with the Icom 746's built-in tuner and will tune 160 (1838 kHz) down to 1.2:1 with the outboard manual tuner.
NB: The AH-4 puts a noise factor into the open loop and cuts way down on its performance according to signal reports. (in m experience, any manual tuner is better than any automatic tuner and gives much better signal reports.)

2. The closed loop with two wire ends. Will tune all bands with the exception of 160. 20 meters can be easily brought to 1:1.

3. 450 ohm feed. 20 m (14070) can be brought down only to 1.5:1

4. Coaxial feed. Better with a 4:1 balun at the feed point than with a direct connection, but still not as good as the ladder line. It cannot be tuned to a lower frequency for which it is resonant (3952). Manually tunable, but with very high SWR's.

You wrote "then using only one end of the loop connected (as in a long wire antenna) with counterpoises on every band."

Could you please elaborate on this setup?

Do you have counterpoises for every band? If so what are they and how are they wired?

Thanks,

KD8LZT

John , please keep in touch, I find this quite interesting. I have a same size loop, delta shaped, feed point 40 ft high, other two points about 30ft, fed with 55 ft of Belden 8237 RG-8 and a 4:1 dual rod current balun. The antenna was trimmed for best SWR at the middle of the 20M phone band after installation. The way I understand it you would need a 2:1 balun to feed it with coax at 80/75 meters.

I am now using a MFJ Versa tuner 3, MFJ-962D

I have been thinking about changing to 450 ohm line this spring so I could use mine for 75M, my 450 feed line would be about 50 ft. I have a homemade Lexan window pass thru, ceramic insulators for the 450 line.

I am surprised it did not go 1:1 on 20m with the 450 line.

What was the approximate length of the 450 line?

Does anyone have any ideas?

Rich ,KDØZZ ,

from the middle of Missouri , out in the sticks with the hicks and the ticks.

For that low height over ground you would need 1:1 in fundamental
On first harmonic 1:2 and on higher bands 1:4
That is what I found out here
I have a fullsized topbandloop fed with ladderline
And I use the line for transforming the low impedance up on 180 and 80 (and
a balun for bring that down to 50 ohms)

Dear Sir,

Thank you for your help. I may be able to set up a full length Skywire. I am not sure if I should aim for the middle of the band when making the lenght. I am also not sure if I can get it up 40-80 feet at all places and hold it very rigid. I am planning on using what most power companies use as power transmission line. The center is a strong steel center surrounded with aluminum. I livce out in the country and the only one I worry about coming into contact with it would be any transoptation vehicle at my home or visitors over 20 feet tall. Would 20 feet be ok? The tower is 89 feet tall. I was planning on feeding it close to one bottom corner.

Thank you again

Michael

From: Michael Shepard
Topic: 3858 Message: 3865

hey folks I'm about to go up with skyloop. Does 1747 ft sound ok for overall length? next question, does each leg need to be same length as others? My legs that I can accomadate are...400' on west to east....480' north to south ....or there abouts....I may cut some lenght on corners to get a higher Hz......I'm not sure about height...may be able to get it up ...not real sure how much....house at tower is at top of rise on hill......all wires go down hill by about 10 ft or so to the east...Thanks Michael.....n5wtr....73's...and thanks...

Dear Sir,

Thank you for your help. I may be able to set up a full length Skywire. I am not sure if I should aim for the middle of the band when making the lenght. I am also not sure if I can get it up 40-80 feet at all places and hold it very rigid. I am planning on using what most power companies use as power transmission line. The center is a strong steel center surrounded with aluminum. I livce out in the country and the only one I worry about coming into contact with it would be any transoptation vehicle at my home or visitors over 20 feet tall. Would 20 feet be ok? The tower is 89 feet tall. I was planning on feeding it close to one bottom corner.

Thank you again

Michael

For that low height over ground you would need 1:1 in fundamental
On first harmonic 1:2 and on higher bands 1:4
That is what I found out here
I have a fullsized topbandloop fed with ladderline
And I use the line for transforming the low impedance up on 180 and 80 (and
a balun for bring that down to 50 ohms)

Dear Sigi......

I'm about to go up with the sky wire loop....I'm trying for an all bands..and it can go thru a tuner if I desire...just turn the knob.. The idea is to get about 375 north to south leg.....and sabout 480 on west to east.. Hopefully I can get it up to a desirable height. All wires will run down hill from house and tower. this drop in height will be maybe 10 ft in 375 ft. not sure what I can use to get it up in height....Money is tight right now. Should I make it longer or will that help any? I can go south as much as 600 ft on eack leg.
power line gets in the way near end...One friend, now a silent key said I may want to tunnel to the ground side near base of power line. I think not..what do you think....he said it makes a big ear..Love hearing from you guys ..I'm 60 and about to go on disability..this will be my only thing to do 'cept ragchew...I appogize so my fist on this key board..Guess I should go on to get my xtra?..I was up to 19 wpm..then someone broke the key and now I don't try much...I may be putting it up 2nite..73's..n5wtr

3867. 800 foot large loop with 450 ohm feed line

Yahoo group: SkyWires
Date: 2011-03-07 15:27:38 UTC
From: MICHAEL AVERY
Topic: 3867 Message: 3867

I use a 800 foot large loop fed with 450 ohm ladder line into a pre MFJ made Vectronics tuner with 160 thru 6 meter coverage that works very well. AC8GN

3868. Loop Skywire vs. GAP Titan DX: A WSPR data study

Yahoo group: SkyWires
Date: 2011-03-07 16:55:19 UTC
From: kp4md
Topic: 3868 Message: 3868

Using WSPR network data, the performance of a 40 meter Loop SkyWire antenna was compared to a Gap Titan DX multiband vertical antenna on 40 and 20 meters. The study data are posted at http://www.qsl.net/kp4md/wspr.htm <http://www.qsl.net/kp4md/wspr.htm>
Carol, KP4MD/W6
CONCLUSIONS
1. The WSPR network data permitted a comparison of signals from two antennas to a distant destination.
2. Over the study time period, the WSPR network data corroborated the VOACAP predictions for trends in ionospheric propagation.
3. The 40 meter full wave horizontal loop antenna produced consistently higher (2 to 11 dB) signal to noise ratio reports than the Gap Titan DX antenna. Differences in radiation patterns and efficiency are probable causes.
4. The 40 meter full wave horizontal loop antenna with predominantly high angle radiation maintained contact while the Gap Titan DX antenna lost signal when the ionospheric propagation changed to a multiple hop mode.
5. The Gap Titan DX antenna offers advantages of simple mounting, compact size and a low standing wave ratio without need for re-tuning on multiple frequency bands, but being a shortened antenna compromises radiation efficiency.
6. The low cost and simple construction loop antenna provided higher radiated signal strengths in this study, but requires greater physical area, multiple supports, and antenna tuning unit adjustment when changing frequency bands.

Topic: 3868 Message: 3869

Facinating post Carol, thanks,

I use a loop horizontal loop up about 12 feet and somewhere between a 40 and 80 meter in size.

I'm always amazed by how well it works on 40 meters when talking to friends each afternnoon throughout the western U.S.

From Alaska to Southern Ca., New Mexico and Utah.

Every time I go to another antenna, G5RV or random wire or low hanging dipole, in the end I always come back to my loop and AH-4 antenna tuner.

Dennis ... AI6R

Subject: [SkyWires] Loop Skywire vs. GAP Titan DX: A WSPR data study
To: SkyWires@yahoogroups.com
Date: Monday, March 7, 2011, 8:55 AM

Using WSPR network data, the performance of a 40 meter Loop SkyWire antenna was compared to a Gap Titan DX multiband vertical antenna on 40 and 20 meters. The study data are posted at http://www.qsl.net/kp4md/wspr.htm
Carol, KP4MD/W6
CONCLUSIONSThe WSPR network data permitted a comparison of signals from two antennas to a distant destination.Over the study time period, the WSPR network data corroborated the VOACAP predictions for trends in ionospheric propagation.The 40 meter full wave horizontal loop antenna produced consistently higher (2 to 11 dB) signal to noise ratio reports than the Gap Titan DX antenna. Differences in radiation patterns and efficiency are probable causes.The 40 meter full wave horizontal loop antenna with predominantly high angle radiation maintained contact while the Gap Titan DX antenna lost signal when the ionospheric propagation changed to a multiple hop mode.The Gap Titan DX antenna offers advantages of simple mounting, compact size and a low standing wave ratio without need for re-tuning on multiple frequency bands, but being a shortened antenna compromises radiation efficiency.The low cost and simple construction loop antenna provided higher radiated signal strengths in this study, but requires greater physical area, multiple supports, and antenna tuning unit adjustment when changing frequency bands.

If you plan to use it on the 3 lowest bands ... put as much wire up as high as possible
On the higher bands you will have a cloverleaf pattern BUT where one of the multiple lopes go there is a lot of signal
So try it out on all bands!!!
Feed that beast with ladderline and a good tuner and you will almost never want another antenna

From: Michael Shepard
Topic: 3858 Message: 3871

Dear Sigi,

I am trying to figure out the length total. I do want to put up as much as possible. The wire I intend to use is the common power wire. It has a steel center for tensel strenght and aluminum outer wrap. I need to weigh lenght vs. return of signal reception. I will try to get a good length. Do I go multiples for 160, mid band times number of multiples. I may be able to put up as much as 2176 ft. Should this a good length for most bands? I can use a tuner if needed. I would like to have some affirmation about the lenght.

Again thank you for your help. I will try to go out and construct some steel towers to hold this wire up high.

73's n5wtr

Your friend in Texas

Mike

3872. AW: AW: AW: AW: [SkyWires] Loop Feed Experiments: Results

Yahoo group: SkyWires
Date: 2011-03-08 21:30:01 UTC
From: Siegfried Jackstien
Topic: 3858 Message: 3872

What i do for such things is ... (made that 3 times here and some times more
for friends on other locations):
Take a google earth view (with that I have the trees in the satellite view)
Measure the length(s) between trees
Model the antenna in mmana
...
With that you can decide if you really want that big big mega loop ... or if
it is better to make it a bit shorter....
I did that modelling with my first deltaloop
I wanzed max gain in southwest direction on 40m
And with trying different setups (56/56/56 and 40/59/69) I could try where
the lobes go on the different bands ...
So what I first would do (prior to digging any hole for a pole)
Download mmana and learn how to use it
You do not need to be an expert on that
i learned how to use it just with playing around with that soft

Been there done that :-)

Greetz
Dg9bfc

Ps .... if weight is a problem (with that beast it will be) use electric
fence wire .... in summer it bends upwards if the field is very warm :-)

3873. PUTTING UP 160M LOOP IN WV

Yahoo group: SkyWires
Date: 2011-03-15 01:54:32 UTC
From: James
Topic: 3873 Message: 3873

IM NEW TO THE GROUP (AND IM NOT SHOUTING, JUST A LOUSY TYPER).
IM PUTTING UP A LOOP FER 160 AS SOON AS THE WEATHER AND SPARE TIME WILL ALLOW.
HAVE LOTS OF TREES AND SPACE UP THE HILL BEHIND MY HOUSE.
FROM ROUGH MEASUREMENTS IT LOOKS LIKE THE LOOP WILL BE ABOUT 700 FEET AROUND.
JUST WONDERING IF THE ADDITIONAL LENGTH WILL MAKE THE LOOP HARD FOR THE TUNER AND OR WILL MAKE THE PATTERN LESS USEFUL ON THE HIGHER BANDS.
I PLAN TO FEED WITH 450 OHM LINE AND HOMEBREW LINK TUNER.
ANY EXPERIENCES THE GROUP HAS WITH THIS SITUATION WOULD BE HELPFUL.ANY SUGGESTIONS?
THANKS,KZ8K,JIM.

3874. Re: PUTTING UP 160M LOOP IN WV

Yahoo group: SkyWires
Date: 2011-03-15 19:57:53 UTC
From: Aaron
Topic: 3873 Message: 3874

Jim,

My loop is cut towards the bottom of 160. I feed it with about 35' of 450 to a balun designs 4:1 and then coax to the shack. My ft-950's internal tuner will get it on any band. Anyways my point is if you get it setup right for multiband the harmonics should be close. The 700' seems a bit big and should be resonant roughly around 400 kHz below the band.

If you are going for multiband with as much wire you can get up then give it a shot. Should work fine as long as the tuner can handle the impedences

From WH2T - Dr. Ace's Multi-Band Super Mini Loop Antenna

Here's how to make the "Super" antenna.
To build this antenna you need a lot that is at least 100 feet across.
(This can be on a diagonal).
Antenna covers all bands 80-10 meters + 30, 17, 12 meter WARC Bands
This antenna works as a Full Wave Loop on 80 Meters and also works as a 2 wavelength open loop or Bi-Square on the 40 Meter band.
The gain is around 4 dBd on 40 mtrs, but it will seem much higher due to
the very low angle, radiation pattern.
Any antenna tuned for 80 Meters should also work on 20 and 10 meters as
well. If an antenna works on 40 it should work on 15 as well. A tuner
will probably be needed for 10, 18 and 24 MHz Band operations.
The loop is an inverted vertical triangle with the base
along the top and what would be the apex hanging down. Or it could be
erected horizontally if needed.
The feed point at the bottom uses a 3:1 or 4:1 balun and is then fed with any needed length of 50 ohm coax.
The top center is broken with an insulator and has a 29 feet 10 inch length of 450 ohm ladder line connected across the
insulator.

IMPORTANT - The 450 ohm ladder line is shorted across at the bottom end.

Here is how I calculated the loop size.
Dimensions -
One wavelength at say 7.25 MHz = 1005/7.25 = 138.62 or 138 feet 7.5 inches.
If this length is doubled and used on 80 meters as a loop
Then Freq(for a loop) = 1005/(2 x 138.62) = 3.625 MHz.
The 1/4 wave stub = 246 multiplied by (Velocity Factor of your type of ladder line) /7.25 = about 32 feet.
Ladder line / twin lead velocity factors vary by brand, type, insulation, etc.
The best method is to use a grid dip oscillator or antenna analyzer to
measure the resonant frequency of the 1/4 wave matching stub during
construction, rather than by just using the mathematical formula to
determine the length.

The perimeter of the 80 meter loop for 3.625 MHz = 277.24 - (2 x 29’ 10”)[2 x 29.86 feet = the length of both sides of the wire in the
ladder line]
= 217.52 ft. Let’s call it 217.5 feet.
If the top horizontal span is made 99.5 feet overall and the legs 59 feet each then the balun will hang about 30.5 ft below the top
center insulator.

The 29’ 10” ladder line can have its bottom - shorted end - tied to the
top of the balun with a short length of fishing line, weed eater line,
string, or cord etc.
On 40 meters the ladder line stub automatically acts as a
switch and opens the connection across the insulator so the antenna
works as 2 one wave length loops fed in phase.
This antenna is a high performance, full size, full wave, 80m loop antenna.
On 40m it is a 2 wave length open loop or Bi-Square.
The stub in the top leg of the antenna opens the loop when operating on 40m and selected other bands.
This improves the antennas radiation pattern.
Its gain is around 4dB, but it will seem a lot higher due to its excellent, low angle, radiation pattern.
The 50 Ohm coax from the balun to transmatch is not critical but recommended to be 1/2 wave length.
(99 Feet of RG-8X)
This antenna could also be configured as a 54’ 4.5” square
on a horizontal plane. The 217.5 ft loop can be pulled into almost any
shape but the bigger the “aperture” enclosed area the better it will
work.
I have NOT tried this experimental design yet. I believe my calculations are correct and should work.
I have heard rumors that something similar to this
Multi-Band loop antenna is available commercially
as a "Super Loop" from R a d i o W o r k s.

UPDATE
The antenna has been built and tested by Don / K8THU.
Here are excerpts from emails I got from Don in Nov, 2005
Hi Ace,
The stub needed to be longer than you quoted.
{Page info has been updated to longer stub}
The other measurements are exactly as you stated.
The antenna is resonant at 7.21 so I could shorten it slightly but have not done so.
I just was on 20 and worked N. Ireland and France again both with 5/8 reports.
I am using just 100 watts with my Kenwood 570 and the internal tuner.
Locally on ground wave on 75 meters I am getting 20 over 9 reports on distances about 300+ miles.
Don, K8THU
Hi Ace,
Ok, on Saturday we removed the 1/4 wave stub and found it was too short so we changed it and then pruned it
until the stub was resonant at 7.25. I did not alter the loop size other than the stub length.
Then we reassembled the whole antenna and found with the extra stub length the overall antenna resonant frequency was 7.21 Mhz.
so I left it there for now and began SWR testing.
The SWR readings are after the stub lengthening.
Ladder line is 14 ga. stranded and the other line is also 14 ga. stranded and insulated

(thnn?).
VSWR Measurement Results follow:
3.995 Mhz / SWR 1.1 to 1
3.751 Mhz / SWR 2 to 1
7.164 Mhz / SWR 1.1 to 1
7.290 Mhz / SWR 1.2 to 1
14.151 Mhz / SWR 1.3 to 1
14.348 Mhz / SWR 1.7 to 1
21.250 Mhz / SWR 2 to 1
21.441 Mhz / SWR 2.5 to 1
24.932 Mhz / SWR 3.5 to 1
24.987 Mhz / can't load
28.331 Mhz / SWR 3 to 1
29.650 Mhz / can't load
Usually I can't load on 10 meters.
40 and 20 are really quite good. Even 15 isn't too bad.
Don, K8THU
End of excerpts from emails.

3881. Questions about 80 meter fullwave loop

Yahoo group: SkyWires
Date: 2011-03-20 20:50:14 UTC
From: N H
Topic: 3881 Message: 3881

All,

I have been a subscriber for awhile, but I am just now getting ready to try out my first loop.

It will be cut as a fullwave loop for the low end of 80m (CW portion), and fed with around 100ft of 450 ohm ladder line. On the shack end, it will connect to a 4:1 balun, and then to a tuner with a match range of around 10:1. It will be a horizontal delta, up about 60ft or so.

I have a couple of questions.

1) Can I expect to be able to use this loop on 60 - 10 meters? If not, what bands would not work?

2) How about 160? Any chance it might tune up there also?

Thanks

Nathan

It probably tune all bands above 80 easily. You might be able to tune it on 160 but don't expect much..I had an 80m loop and increased the length to almost resonance in the 160 band. It tunes everything from 160-6 meters. I have a rough spot on lower 75 m band but it tune with patience..good luck, Alan

You can maybe ad a remote switch opposide of feedingpoint and use the loop on 160 as "bent" dipole .... a friend had the same problem ... only room for 80m loop .... he made the feeding outside in the backyard ... so that the other side of the delta is close to the house (actually it was about a few feet from his window) .... so with a jumper he could close or open the loop ... that also effects lobes on the higher bands (he told me) ... so sometimes on 40 or 20m he closes the switch and sometimes it is open.... On funsamental frequency (80) the impedance of the loop will be way lower as on the higher bands ...

Topic: 3881 Message: 3884

Your 80 meter full wave loop should work up through 10 meters. But as you will using a BALUN and tee network tuner you may have some frequencies that are hard to tune and apply full output power too due to complex reactance's/high voltages. You may also get some RFI in the shack.

I have a 300 foot long loop up in a square configuration and supported 35 feet up at each corner, fed with approximately 45 feet of 450 ohm window line and it tunes 80-10 perfectly with no touchiness or RFI. However I use a balanced link coupled Johnson Viking Matchbox tuner and that's the best way to go for an all band loop.

The antenna will not work on 160 meters because it's an RF shorted out half wave on that band and just a big air cooled dummy load. However if you let one end of the window line float then you will have an end fed horizontal wire that will work well as a high angle radiator out to approximately 800 miles. But as you are using coax between the BALUN and tuner you can't do that.

From: ke6vhm
Topic: 3885 Message: 3885

Good day to you all. My lot will easily allow for a 558 ft loop (1160M). Actually there is more than that, but I dont want to go around the front yard. Room for about 592 ft goes all the way around the back yard, pool, house and part of the driveway, I will cut this back to the 558ft. This will be a rectangle (137+142x2=558) fed in the middle of one of the 142ft runs with ladder line. I am thinking of 24 ft off the ground and feed will be almost straight down to shack, I can make it straight if what will be better.

Havent decided on how run the feed into house yet.
Three options I figure.

1. Ladder line all the way to the Dentron Super Tuner through a window escushion made out of Corion counter top material (this is already in the sliding glass window and all the current coax leads and my ground goes through here) then coax to rig

2. Ladder line all the way to the wall below the sliding glass window then through the wall with porcelen insulators then continue the ladder line to the tuner coax to rig

3. Ladder line to a balun (if i do this what ratio of a balun?) to coax to Dentrom super tuner

4. you tell me

So your opinions please. Specific question I would like answered since the area (WxL) is determined by area available are these.

1. Will the feed going to the middle of one of the flat sides instead of a corner adversly effect the antenna in any way?

2. Which feed system would work the best? Now worried about how to dodo this - just which one?

3. Is there anything wrong with the 24' elevation?

4. Should I worry about the feed line going perfectly straight or would a small amgle be ok?

I will be running

Kenwood TS520 or Icom706 probabally 100 to 600 watts

If you need anymore info let me know

Topic: 3885 Message: 3886

Feeding in the center instead of a corner will have little effect, some minor shift of the lobes. The Dentron tuner uses a balun IIRC. I would keep any coax to a minimum as some freqs will produce high voltages at the end of the feedline and increase losses. I use a Dentron MT3000 now with a 4 to one balun feeding ladderline to a 176 foot dipole.
When I finish my house on 3000 SQ meters of land I will have a 160 loop up also. A run of ladder line to the house, slight leaning but no sharp turns, to the 4 to 1 balun under the eve of the roof and short coax to the tuner. I will use 10 meter long bamboo poles to support the loop.
The house sits on a hill about 60 feet above the lower flat ground. So in the prevailing direction of the loop I will be about 30 feet at the distal (far) side and 90 feet at the proximal (house) side. The far side wil be to the NNE from the house. That should hit most of NA and Europe with main lobe.
From all I read and experiences of others, I believe you should have no problem on the higher frequencies with a fairly low takeoff angle. On 160 and 80 it will be a NVIS but still offer some DX opportunities.
So GO FOR IT!

Don HC4/W4BWS

My plan is to run the ladderline direct to the tuner and a very short run of coax to the rig. the feed line will be approx 22 feet long to the tuner and almost straight down, there will be a small turn to get in inside the house. I shouldn't need a balun outside since there is one in the tuner. Right?

Don - you mentioned a "balun IIRC" What does that acronim stand for please.

Thanks in advance for any answers to these.

The acronim IIRC stands for "If I Remember Correctly".Yes you should be good- to-go with your plan if there is a balun in your tuner.

3893. PUTTING UP 160M LOOP IN WV

Yahoo group: SkyWires
Date: 2011-04-10 23:18:28 UTC
From: James
Topic: 3893 Message: 3893

An update on the loop project WEST VIRGINIA....the loop is up, and doing great.Started out with 570 feet total, up about 40 feet.After a frequency and reactance sweep , the loop showed to be too long....with a zero reactance at about 1700 khz ,I decided to shorten it about 30 feet.
Possible due to the vynl coating of the 12 guage stranded wire or due to the back side of the loop being only 30 feet up, the formula of 1005/freq. was off a bit.
After removing 30 feet (and having to change two support positions),another sweep of frequency vs reactance was done.
Now the loop has a zero reactance at 1800 khz ,3630 khz,7270 khz,14500,and 27500 khz.(dont have much use for the last one.)
NOW TO THE QUESTION FOR THE GROUP....
Although the reactance is zero at those frequencys,due to loop radiation resistance the SWR varies from about 2.5 on 160m to about 7.0 on 20 m.
Would it be acceptable to feed with coax and the small loss increases due to the mismatch ??
The feed line is only about 60 feet long of RG-8U.
Any input or advice would be appreciated.
thanks,de KZ8Jim.

Thanks don for the reply...well loops ARE resonant just like any tuned circuit.
There are cyclic values of reactance and radiation resistance....they are not a rhombic type antenna.
If one can establish a desirable zero reactance frequency , at all harmonics of that frequency another zero reactance will occure.
While a tuner .is a wonderfully useful device, i prefer to make it as easy as possible for it to do its job.
As the frequency goes up the loop radiation resistance goes up...swr increases and matching can get harder.
Having a large value of reactance with this swr just makes things more difficult for marginal tuners, such as internal or external auto tuners.
While one can simply ignore all this, i prefer not to.Thanks.

3896. Will It Work?

Yahoo group: SkyWires
Date: 2011-04-11 20:20:35 UTC
From: Doug Fitts
Topic: 3896 Message: 3896

I am a newbie to the list, was suggested to install a Skywire Loop antenna as opposed to a G5RV I had planned to install. I did the research and will later do an exact dimension/measurement on my property later this afternoon. My notes tell me that this antenna is a full wavelength in most cases cut to the 80-meter band using the 1005/freq formula. for all band operation [10-80 meters].

The height of my single story house is about 18 feet at the highest point [middle] according to the limited house floor plans I have. The best I can do [if necessary] is put up a monopole at 15-20 feet at each corner with, two poles high enough to clear the roof at the north end of the house, each leg running about 56 feet in wire length in a square configuration. I have no trees on my property and a HOA spy team to contend with every now and then. So stealth is the name of my game as best as possible.

The equipment I have to play with is a Kenwood TS-440S and TS-520S HF radios, a Dentron "Super" tuner, a decent ground system leading into the shack and a Bird wattmeter in the line, eventually. Any suggestion on the above, will the dimensions work at the over all length of 224 feet [square]?

How do you get a decent ground system with the water table 5000 feet below
ground?
Last I knew there were 2 wells in that area one owned by a motel?
I wish you luck keeping it hidden, might help to use TAN electrical wire so
it blends in with a artistic touch of green paint here and there, until the
birds find it to roost on.

1998?...been a long time since you've been out this way to be sure. Vail Arizona [a suburb of Tucson] has really built up quite a bit with several new "sub-divisions" in my area, mine included. We moved here in September 2004. Water table at 5K depth? Not aware of that but, my ground rod is down over 10 feet [long story how it got that far]. With a 20M dipole up and my TS-520S wired in with the tuner, I have no issues with tuning on 20-meters.

So at some point I will put up a new Skywire Loop or an equiv. Yes, out here the HOA is "the boss" when it comes to certain aspects of our community. I have not approached them to put up any antenna in almost seven years and do not plan too!

--- In SkyWires@yahoogroups.com, Adrian Flynn <ADRIANJAMESFLYNN@...> wrote:
Unless my recollections is faulty (It might be) the last time I was in the Vail area (1998 when we rebuilt the Grand Canyon Airport and kept it open for normal operation at the same time AND most of the roads in Vail area also) it was a wide spot in the road to the Grand Canyon, When did it get high fa looting enough to have a dad blamed *HOA*?.....How do you get a decent ground system with the water table 5000 feet below ground? Last I knew there were 2 wells in that area one owned by a motel? I wish you luck keeping it hidden, might help to use TAN electrical wire so it blends in with a artistic touch of green paint here and there, until the birds find it to roost on.

I noticed your callsign on this list as K7SVU. Looking it up on the QRZ website it shows no record. However when I plug in your new callsign [below], I see you recently got a new license and callsign and living in another state. Curious why you vacated our beautiful climate out here?

I can breath in MI!
I originally moved to Phoenix, AZ in 1952 from PA as I could not breath there due to asthma.
I spent the next 30 or so years in the valley more than 80% of the time.
I then moved to Holbrook for the same reason I moved to AZ, and the same reason I just moved to Lansing, MI.
I am on O2 24/7/365 in MI 2 LPM in AZ just before I moved in March I was on 5 LPM and could not walk across the room without being short of breath. Here in MI I can walk around all I want, do LIGHT physical work and enjoy my 2 1/2 Month Granddaughter!
I hope to see her grow up but with 5 stents, on my second pacemaker/defibrillator, type 1 diabetes, COPD, Sleep Apnea, Nerves dying for diabetes, in both legs and one arm well I don't think I have much chance.
K7SVA is what my call would have been if I had upgraded from KN7SVA if you find a 1963 to 1965 callbook it should be in it as I got it in late 1963. Of course at that time you could not renew a Novice license and Girls got in the way.
Got my Tech in 09 and I hope to find an exam site I can get to here in MI. (I don't drive anymore) And I am thinking of going to K7SVA for vanity.

As for Vail I am thinking of the one north of Williams on the road to the Grand Canyon, it is at the junction of (AZ 180?) to Flagstaff.
It has a planes of fame air museum and a "Flintstones" tourist trap. The Air Museum has Gen Douglas MacArthur's personal "Super Constellation" on display.

So I only made a 350 mile error, that is almost as good as Google Maps for where I use to live in Sun Valley 10 miles east of Holbrook.
If you google sun valley AZ you will end up in "Star Valley" 15 miles East of Payson, but if you google "Navajo Sun Valley, AZ" you will find where I use to live. An error of 100 miles! and it only took me 6 years of fighting with google to get that far but they still will not remove the error.

You ought to be having real nice weather about now, we are running for 25 at night to 80 days and all over the place in between which is about the same as Sun Valley, AZ although they got MUCH colder than MI did this winter they hit -30°F for almost 2 weeks in December at night and maybe 20°F Days.

Good luck on your Stealth Antenna Project.

WOW...looking at the map you are right smack dap in the middle of Michigan and only a few miles from "Motor City" [Detroit]! We have a few things in common Adrian. I am also from the east coast ["Nu Yak"] as my Boston friends say it. Born in Manhattan, went to high school in Da Bronx, got my Ham tix in 1959 as a young snotty nosed skinny kid with an attitude. That was 50+ years ago.

Today I am a type II diabetic on oral meds with high blood pressure now over 10 years, quit smoking 15+ years ago and gained a bunch of weight and holding on. Drove a city of Tucson bus for over 15 years until I retired April 10th 2009. I think it was the stress dealing with the public that got my BP elevated. Us "old geezers" [I'm age 67+] and you are only 3 years behind me.....have our good days and bad days to be sure. I am beginning to get the loss of feeling/tingling in the feet so things are changing.

Antennas....to get back/stay on topic.

I have a 20-meter dipole almost up and connected. We had rain all weekend so that stopped me from completing the antenna project. I am very interested in this Skywire Loop antenna arrangement but not sure if my property and "attitudes" of the "HOA Police" can handle the addition.

So far I've got no complaints from the neighbors and HOA people with my VHF and UHF antennas and other "stealth" antennas but, I do get once in a great while a written "notice" to cut the weeds in the front yard. Other then that I'd love to put up a 50 foot Rohn tower, a full size HF yagi and attach a couple of inverted V antennas to the tower but sadly....

Not in this life time!

However Adrian, I will look carefully at this Skywire Loop deal and see how best to install one. So far I've read that it out performs a typical dipole in many cases and that is interesting.

Its now 7:45pm PDT so its time for some chow and the wife just got home from the saltmines so I need to hold her hand for a few minutes and see how her day was. Will be in touch amigo.....73

Doug W7FDF

PS: congrats on the 2.5 month old granddaughter. I have four teenage/semi adult/think their grown grands through my son [3] and oldest daughter [1] in Florida and Georgia and I think we may have another grand "in the oven" with my youngest daughter in Seattle in the coming months.

From: Siegfried Jackstien
Topic: 3896 Message: 3903

Fed via ladderline it will work 10-80
If you do not close the loop (or make a switch on other side) you can use it on 160 as a "bent" dipole (better as nothing on 160) ...
The lobes on the higher bands will change if you open or close the swizch (but can be tuned on the higher bands in both cases)
So no room for 160 loop?
Make an 80m loop with a switch ... fed via laderline
Hope that helps...
Dg9bfc
Sigi
Ps YES it will work :-)

Like I said in my first post it might help to use "tan" colored electrical wire 14 Ga or 12 Ga, you can normally find it at a commercial electric supplier in either solid or stranded.

So far I've got no complaints from the neighbors and HOA people with my VHF and UHF antennas and other "stealth" antennas but, I do get once in a great while a written "notice" to cut the weeds in the front yard. Other then that I'd love to put up a 50 foot Rohn tower, a full size HF yagi and attach a couple of inverted V antennas to the tower but sadly....
I don't have any antennas up here yet we are still unpacking and cleaning as this place was not ready like it was suppose to be and we may be moving again soon if some things don't get done fast! We are going to have a talk with the owner today when he comes over. Found out he is not renting this place legally by MI laws LOL.

I would love to put up a tower and such also but on a disability income that is "Not in this life time!" as you say.

Not in this life time!

I do hope to have a MOPA completed and my SX-129X ready by the time I take my general next month (Some place some how)

However Adrian, I will look carefully at this Skywire Loop deal and see how best to install one. So far I've read that it out performs a typical dipole in many cases and that is interesting.
I think a friend of mine that lives east of Holbrook has one of them up, K7JDL Jeff Lineberry (He and I took our techs at the same time both missed one question and the same NUMBER on the test but we had different tests! He took his Gen last year (I was suppose to go with him but I was in the Hosp having a failed pacemaker replaced) and on that one he scored 100%
Its now 7:45pm PDT so its time for some chow and the wife just got home from the saltmines so I need to hold her hand for a few minutes and see how her day was. Will be in touch amigo.....73

Doug W7FDF

PS: congrats on the 2.5 month old granddaughter. I have four teenage/semi adult/think their grown grands through my son [3] and oldest daughter [1] in Florida and Georgia and I think we may have another grand "in the oven" with my youngest daughter in Seattle in the coming months.

This is my wife's first and my fourth (That is 2 more books) and we are as proud as can be which is normal but never decreases

I will keep in touch with you and as soon as I have my general and an antenna up will try to contact you.

Hi Doug,
I'm also transplanted from NY, born in NY Hospital on York Ave, raised in the NE Bronx, licensed in 1970, I loved to visit Barry Electronics before I moved out of NY in 1976.. it was terrible how he died in that boating accident. Was also active duty Navy MC 83-87, then reserves till 91 and in Navy MARS.
I am very satisfied using a Loop Skywire in a motor home park in Northern California. I don't have room for a full 80 meter loop either, so I made mine 140 feet for 40 meters. It performs very efficiently on the harmonics, but less so off the resonant frequencies. I feed mine with a length of speaker wire to keep it stealthy.
Photos, sketches and all details of testing and results are posted on web page http://www.qsl.net/kp4md/kp4mdnec2.htm <http://www.qsl.net/kp4md/kp4mdnec2.htm> if you are curious. Everyone has their own preferred version of this antenna, but for me the Skywire beats any fan dipole or vertical I've ever used.

Well, as they say, "We Are All From Somewhere Else!!". I just looked at your link on the Skywire Loop antenna Carol and especially the construction aspect. I cannot wait to really sit down and look over all of the information presented.

Right now dinner [that I cooked] is ready, the wife just got home from her "place of economic worship", so we need to hold hands and partake of what is commonly called....chow! Thanks nonetheless for your input in this regard.

73

Doug W7FDF

PS: I know New York Hospital very well, on York Avenue [on the east side of Manhattan]. My wife's nephew worked out of that facility as a MD in training. Also, I worked from 1968-1973 [just after I got out of the Navy] at The Rockefeller University [I am sure you know the institution] right down the street on York Avenue and 66th Street. So many years ago and strong, positive memories at that location to be sure.

Topic: 3911 Message: 3911

I made a 4:1 Guanella current balun last year, used PVC pipe and caps , worked great at first. Then after the last contest I noticed the SWR was off above 40M. I took it down and replaced it with a extra voltage balun I had. Cut open and of course destroyed the balun, it had condensation in it .
I made a new balun , with SS eye bolts and hardware, added two 1/16 drain/vent holes in the bottom , installed it in a PVC box with a removable cover. The packing is a closed cell foam so it won't hold moisture. Pictures of the new one are at.

This happens because the original group owner went/is AWOL and apparently forgot his password to get back in if he wanted to and left the current moderators without the ability to change the group so it would require approval to join; so anyone can join, post what they want and leave if they want. That happened this last time. All we can do it delete the unwanted post and ban the offender for the next time, but all they would have to do is change their user name and . You see where that□s going.

There is another group, LoopSkyWire where the group owner IS present and allows his moderators more control, and if you join you will have to be approved so that greatly slows down the hit and run posters like what just happened.

hello Dave,

thanks for your reply. I will stay put here as well but in meantime I put in a request to join the group that you mentioned.

3930. New Balun Question

Yahoo group: SkyWires
Date: 2011-04-26 15:50:28 UTC
From: Richard Schmuke
Topic: 3930 Message: 3930

Over the weekend I took some SWR reading with my MFJ-259 for my friend K2HT on his newly erected 80M loop. It is installed with newly purchased but old style W2AU balun. It has great readings on 20 thru 80m. This should not be, so I did some research on the W2AU single rod type balun. Thru the years many people have worked with this balun but it has its faults. In W2FMI's book he tracks the drop off of impedance change as the frequency declines. The balun is a good 4:1 at about 5MHz and above but drops down to a 2:1 around 75/80M. Now the 80M loop comes into play it is a 100 Ohm antenna on 80M and a 200 Ohm on 40,20 &15. Well the "defective" balun fills the bill for matching with a run of 50 Ohm coax. The W2AU balun is made with 1/2 dia ferrite rod and 14ga wire. So I whipped out some 1/2 ferrite rod and magnet wire and made one the same style. I do not seem to get the impedance differential change I was hoping for. I moved the center resonate of the balun from 3 MHz (11 bifilar turns) thru 10 MHz (6 B turns) but could not get the 2:1 at lower frequencies. Has anyone else played around with baluns, I just can't bring myself to buy one to try it.

Don , WN9V put me on to some good reference material on baluns so I guess I will set the 4:1 rod type aside for today. The http://www.dxengineering.com/TechInfo.asp web site noted that a loop is better off with 300 Ohm line than 450 so I made a mount for 300 Ohm to my loop and will try it when the rain stops. Pictures at http://s1102.photobucket.com/albums/g453/KD0ZZ/ Listed as 300 Ohm Dipole

Rich , Kd0zz

Subject: Re: [Antenna_Builders] New Balun Question

Rich,

Thank you for sharing your findings. There is no
substitute for actually trying things as you have done.

To supplement what your experimental results, there is
a lot to be learned in the group of articles "Baluns
and Feedline Chokes" at

http://www.dxengineering.com/TechArticles.asp?ID={F83E1548-CC69-4C10-A037-5C47A4B645C2}

he even goes into baluns applied to various types of
loops.

You may wish to look over the author's other works
under "technical articles"

http://www.dxengineering.com/TechInfo.asp

Look around his articles and you will find
recommendations for feedline lengths, a factor that is
often overlooked.

3932. Quick Change Dipole

Yahoo group: SkyWires
Date: 2011-05-07 15:59:33 UTC
From: Richard Schmuke
Topic: 3932 Message: 3932

I like to change and play with antennas. I am getting ready to hoist up a 80/40M dipole but with my mind there is no telling what I will try next week. It is a problem running out into the tall grass sometimes and doing a adjustment at the ends. In the summer I get a lot of chiggers so I made the center of my dipole into a quick change with a couple of split bolts. I can drop the center support and do not have to unsolder and re-solder. If that is not clear I added three new pictures at http://s1102.photobucket.com/albums/g453/KD0ZZ/

I have the late W2FMI's book and take what he says as gospel. It certainly does go against a lot of what folks put on the internet. He did back his work up with actual experiments instead of just winding a few wires on a toroid or rod and thinking it worked great. According to his book a lot of what the "experts" tell us is not true.

James , I also refer to Jerry Sevick's book's as my main reference. A week ago or so I wrote about a check I was doing on my friends 80M loop, with a W2AU 4:1 rod type balun using a MFJ259 and found good readings on 80M as well as above. In W2FMI's book , Understanding , Building and Using Balun, on page 32, figure 7-4 he shows a chart where the rod type balun drops off in impedance below 40M. So it would work with a 200ohm antenna at 7+ and a 100ohm antenna at 3.5MHz. I tried to duplicate this with different tries of a single rod balun. I got more even readings so I did not get the same results as he did. It was made on a ½ dia rod the same size as W2FMI and W2AU used , I will try some 10mm rod stock next try and change spacing between the adjacent bifilar turns. His books are my guide also but I do enjoy winding a few wires now and then.

3936. Correct balun type - voltage or current?

Yahoo group: SkyWires
Date: 2011-05-24 15:17:56 UTC
From: Mac
Topic: 3936 Message: 3936

What is the proper type balun for my application, 4:1 Current balun or 4:1 Voltage balun?

I have a full wave 80m skyloop (~ 287' #12ga AL fence wire) fed via (~35') 450ohm ladder line. Prior to entering the shack, the ladder line is coiled into a 9" loop of 3-4 turns (as an RF choke), then hooked to a 4:1 voltage balun. From there, I have a 3' piece of coax that enters the shack and connects to my antenna tuner.

In researching baluns lately, I'm a little concerned I have the wrong type balun in my setup (voltage vs. current). Additionally, I read one article that advocated NOT coiling ladder line as an RF choke - so, I'm a bit confused.

Any help and comment greatly appreciated.

Mac / K6OVI

3937. Re: [SkyWires] Correct balun type - voltage or current?

From: DR Don
Topic: 3936 Message: 3937

Mac, Take the coil out of the ladder line. Take about 20 feet of coax and wind in on a form of 4 to 6 inches diameter. Attach the ladderline to one end and the coax to the matchbox on the other end. The coil of coax will hopefully keep the RF off the coax into the station. I have operated loops and flattop antennas this way with good results multiband.

Dear Mac,

I agree with Dr Don. The coil of coaxial cable he describes is a choke that serves as a Guanella-type 1:1 current balun. Voltage baluns become lossy and fail to keep RF off your transmission line when an antenna is not symmetrically balanced or when an antenna is operated away from its resonant frequency. Current baluns are superior under these conditions.

I've written about my experience with these at
<http://www.qsl.net/kp4md/kp4mdnec2.htm#balun>

Mike,

Are you wanting to make make something or get a commercial antenna?

Also not sure of you lot size which could be an issue with ground radials. So if you limited to a vertical antenna with no radials that proposes another problem but not unachievable. In which case you need no think about a small end-fed antenna.

Something like this...
http://cgi.ebay.com/ULTIMAX100-END-FED-HF-ANTENNA-6-80-METERS-1500W-PEP-/270730925072?pt=LH_DefaultDomain_0&hash=item3f08d21410#ht_1892wt_857

I dont think thats worth buying but but it gives you a general idea. I'm pretty sure its just a wire attached to a 4:1 or 9:1 UNUN

Put the wire inside a fiberglass mast and away you go. On the flip side Zero-Five make a "No Radial" Vertical as well which seem to be getting fairly good reviews.

http://www.zerofive-antennas.com/content/multiband-foldover-10-40-meter-24-foot-no-radial-stealth-vertical-hoa-and-deed-restricted-ha

Anywas there are my thought... still up for debate.

From: Paul
Topic: 3939 Message: 3941

I hope this isn't too OT but because you mentioned flag poles, I thought I read that in 1996 the FCC passed a law that a person is allowed to have a TV antenna on a mast and that right supersedes any HOA rules or CC&Rs, as long as the Antenna is no more than 12 Ft above the roof line. And the person must, as much as possible, cooperate with the HOA or CC&Rs as far as placement - i.e. must be in the back of the house rather than the front yard.

If that is true, That "mast" that holds a TV antenna on top - I think we call them capacity hats - is the start of a vertical.

Or am I mistaken about the fact that HOA and CC&R's can't shut you down?

73,
Paul

> Or am I mistaken about the fact that HOA and CC&R's can't shut you down?

I am no expert here, not by any means. But I haven't heard of an FCC rule that overrides HOAs and CCRs.

There are things that TRY to make it possible to participate in your hobby. And I think some of these are state-wide, not country-wide.

But in the end, if the document you signed when you took on your lease says "no visible antennas", it's what you agreed to.

3943. 1/2 Mile Loop?

Yahoo group: SkyWires
Date: 2011-06-10 20:36:47 UTC
From: Aaron
Topic: 3943 Message: 3943

So I was talking to my neighbor and there is a good chance I can use his property and string up yet more wire... nearly a half miles worth. Would make it roughly a 5 wavelength loop at 1.8 MHz. The 2 major obstacles are that

1: I need to span about 645' of cornfield high enough not to pose a problem to any farming. This shouldn't be to hard if I have some really well mounted pulleys in the trees and come alongs to keep up such a high tension on the loop.

2: The feed point will be around 360 from the house. I guess the only way to feed it would be with 400 or even hand made 600

There are some other considerations in the back of my head in regards to NSD and lighting protection on such a monster.

Not too sure of the practicality or performance would be either but looks like one hell of a fun project if I get the go ahead.

No ... ladderline and loop are balanced ... so earthing one side is a bad idea
At the point where you go from coax to ladderline (balun, tuner, whatever) there you can ground the coax (and depending on your setup the loop too via the balun or tuner)
A 1:4 (voltage) balun (as an example) has one side direct to 50ohms input ... center is grounded ...so dc wise you have a groundconnection for the loop
Okay a direct hit would burn up your balun BUT direct hit would burn up nearly everything :-)

The only thing I have ever heard of remotely doing anything like that on these big antennas is to tap a resistor off to ground to dissipate any static build up. But I was only told that by one person in a casual conversation so I'm not sure the validity of it.

Ooops! It occurred to me that grounding one end of a loop would also ground the other end.....being as they are both the same piece of wire...
On the other hand, some mobile antennas have a resistor "shorting" both sides as it goes into the coax, as was mentioned.

Using a large value resistor to ground is a perfectly valid, and good,
thing to do whenever your antenna has no DC path to ground. It bleeds
off static, which can build up from wind and rain.

For a balanced antenna/feedline, use two equal resistors to ground.
Don't disturb the balance.

Make sure to do calculations to tell that their power rating is
sufficient not to overheat when you transmit.

Alternatively, one could use inductors to ground (again, a pair to
keep it balanced is best), with enough reactance so they don't shunt
your signal too.

The resistors don't protect against nearby lightning strikes, which
induce a sudden voltage spike and can sometimes damage equipment. For
that, use lightning suppressors. I've seen a pair of spark plugs used
for that. Even they won't protect against a direct hit.

Nothing will..

I had a strike go through my lab. Here was the path:

Second tree over to the right... yup, it bypassed a tree right next to it.

Into the (or out of if ground up) metal vent in the gable.

Down a 2X4 stud, blasting half of the wood off across the lab for about 7 inches.

Down through the wood top of an antique radio. Too much stuff right now to move that to see what else it did.

But wait... it branched off through the middle of the air in the lab, right to a metal grounded band on a small Radio Shack AM-FM tuner.

Through the ground side of that tuner into the electrical wiring, into the house causing a temporary black out.

The AM-FM tuner still works great.

A small Radio Shack AM radio, the last of the "Flavoradios" for some reason now has no RF. I get noise, and even can inject an IF signal, but it no longer recieves radio signal.

It's all on one chip. Can't find the chip anymore (no longer manufactured). Crazy how the EM radiation from that strike only blew out that radio.

If I were in there that night as I had planned, I would likely never be able to tell you about it.

Gabe

3956. "terminating resistor?"

Yahoo group: SkyWires
Date: 2011-06-28 22:26:51 UTC
From: Steve Eisenberg
Topic: 3956 Message: 3956

How about using a terminating resistor on the loops? B&W uses them on their folded dipoles, which look like squashed loops to me.
Thanks,
SteveKA1ZFY

> How about using a terminating resistor on the loops? B&W uses them
> on their folded dipoles, which look like squashed loops to me.

The B&W folded dipole is a folded dipole, and a folded dipole is NOT a loop.

Yes, a folded dipole appears electrically in the form of a loop, but
folded dipoles do not work at all like loops work. They behave like
dipoles, with a built-in impedance transformer. The currents in the
two adjacent wires are essentially the same (in magnitude and phase),
not like a loop. The performance of a loop depends on the area
enclosed by the loop. But a folded dipole can enclose zero area.
Loops don't work if you do that.

How much the TTFD or T2FD (which is the name for the B&W folded
dipole) behaves like an "ordinary" folded dipole, I can't say. But I
think it's fair to say it behaves more like a folded dipole (and
therefore a plain dipole), than like a loop.

I think I have seen terminating resistors used in large loops too,
giving them some degree of directionality which they otherwise would
not have had. I think they were used in receive-only antennas.

Rhombic beam ... 2 v beams pointing to each other on the ends ...
Or a very large loop .... gives BIG gain in 2directions without terminating resistor .... unwanted backlobe is suppressed with adding that resistor on one end

3962. Antenna question...

Yahoo group: SkyWires
Date: 2011-07-06 12:30:06 UTC
From: kg4coq
Topic: 3962 Message: 3962

Hello.
Heres what I have for you today.

Two antennas,Number one is a Cushcraft R-7 Vertical. On a tripod,approx. 42 ft to very top to ground. (antenna built is 22 1/2 ft long itself)

Due to location restrictions on property,antenna number 2 (a 3/4 wave,22 ft 2 mtr fiberglass repeater antenna) is to be located 11 ft away on a small tower with total height of approx. 50 ft to very top to ground.

Question is will this setup interact with each other in any way ?
Not so worried about the 2 mtr but I am worried about the R-7 vertical. I realise the antennas themselfs will not interact due to freq. spacing but will the structure locations throw the R-7 pattern off ?

Please reply back directly to email address below:

From: Siegfried Jackstien
Topic: 3962 Message: 3965

Will they interact? ... yes ....
Will the interaction disturb the pattern ,,, yes ,,,, but only very little
... so you will not notice it ...
Problem could be that swr on some bands will be a bit different than without
the other antenna so close ... but I think you should just use it and see
the results

FYI, I don't know but I sure would try it. My 80m delta loop has two legs a little longer than the far end but it still has good reading on 40 thru 10 with a 4:1 current balun. I put up the ropes into some trees and pulled it up.

I lowered it for a ice storm during the winter , then pulled it back up reading were a little off so readjusted a support on one side a few feet and all is fine. I don't think you will really know until you try one.

Rich , Kd0zz

Jim,

Shape is really not important - enclosing the max area possible is what you are shooting for. The "best" shape is a circle, but that's just not practical. Square is next, then rectangle, then triangle.

I have a full wave loop cut for 80m strung in trees in my back yard (~285' of 14ga AL electric fence wire - $20 for 1/4 mile roll at Tractor Supply). Due to where my trees are, my loop is a fairly narrow rectangle and is maybe 40' high in one corner and as low as 25' in another corner. I'm impressed with how well it works even with a branch touching it and the occasional gob of Spanish Moss draped over it (I'm in FL). (I do try to fleece the moss off it once a month or so) :)

I'm feeding it via 450 ohm ladder line and use a 4:1 balun to transition to a 3' piece of coax to get it into the shack and to a tuner.

Hope this helps,

Mac / K6OVI

Hi Mike,

I saw the inside of the MFJ-912 in an article by the late L.B. Cebik, W4RNL. I believe it uses (2) T200-2 iron powered cores with 11 to 12 bifilar turns of wire. This is very similar to the balun that was used in the Heath SA-2060 antenna tuner. The balun used in the Ultimate Transmatch used (3) T200-2 iron powered cores. I am using a T300A-2 iron powered core with 17 bifilar turns of 14 ga wire with teflon insulation of the Ruthroff design in my homebrew T-network tuner. The core is three inches wide by one inch high. Many commercially made 4:1 baluns are using this design now.

A great book on baluns is "Understanding, Building, and Using Baluns and Ununs" by the late Jerry Sevick.

Good luck,
Garry - K4OR

Well I can't comment on that specific Brand/Model of balun but so far I have found I prefer feeding my loop with about 35' of 450 ladder line and a good 4:1 balun. I'm about to reiterate the antenna at a friends house next week.

Anyways with the 4:1 it will allow for mutliband use as long as you are resonant around 1.8 to 1.9 without a need for a tuner.

That is a W9INN design and from what I have read its a voltage balun. Hook it up and try it out, it may work well. If you need to upgrade to something a little better I might suggest a Balun Designs one. I use a #4124 and it works great, about to put a loop up with a #4115 for a friend to see how it works.

Another great balun is the Palomar Model BA-4-1500 4:1 Balun Kit. It is a brute, and can handle most anything you can throw at it, even at the highest power levels. Check it out at:

http://www.palomar-engineers.com/4_1_Balun_Kits/4_1_balun_kits.html

I have one here and intend to mount it inside of the high power antenna tuner I am building. Of course you can put it in a weatherproof box and mount this balun anywhere. Although there is no enclosure, this kit is half the price of the MFJ-912 balun. All things considered, the MFJ enclosure must be very expensive :)

Just another option to try, if you'd care to save some money.

Best regards,

Gary, K7EK

If you need to upgrade to something a little better I might suggest a Balun Designs one. I use a #4124 and it works great, about to put a loop up with a #4115 for a friend to see how it works.

Mike,

Here is a link to the W4RNL article I mentioned previously.
http://cebik.com/content/a10/trans/41balun-3.pdf.

This shows a picture of the interior of the W9INN balun.

3980. 4:1 + 1:1 Balun

Yahoo group: SkyWires
Date: 2011-07-22 12:05:34 UTC
From: Richard Schmuke
Topic: 3980 Message: 3980

The other day I was working on a 450 ladder line set up. I made a indoor 4:1 balun to go between my tuner and window feed thru. Several people had questions or suggestions. The last critique was that sometimes you might need a 4:1 balun to match a doublet or a multi-band loop and other times you might need a 1:1 balun.

So I made a set up with a switchable balun, a 4:1 and 1:1 together. The first two pictures are of my set up. When the days get down below 100 degrees I will change the outside stuff.

I looked the pics ... awesome :-)
If I have seen it right in 1:1 you parallel the 2 baluns and in series ... right??
Dg9bfc
Sigi
Ps what the hell type in "google" to find those nice switches??

Switch “google” is switch knife dpdt or http://www.allelectronics.com/make-a-store/item/SWS-13/D.P.D.T.-KNIFE-SWITCH/1.html. or cheaper at

http://www.skycraftsurplus.com/knifeswitchdpst-1.aspx

My switch came from a hamfest junk box.

A very good drawing of my lay out for the switch can be found at

http://www.angelfire.com/electronic2/qrp/balun.html

Don’t worry about you question , I understand what you mean, the problem is the time lag between your time zone and mine. I looked at the pictures and if you need a better one of the switch wiring I can take one but the link I sent is good for the switch, it just shows a torrid and I used rods.

Rich, Kd0zz

PS: I hope Vettel does good in his home land this weekend.
